#### Abstract

We show that the porous medium equation has a gradient flow structure which is both physically and mathematically natural. In order to convince the reader that it is mathematically natural, we show the time asymptotic behaviour can be easily understood in this framework. We use the intuition and the calculus of Riemannian geometry to quantify this asymptotic behavior.

## 1 The porous medium equation as a gradient flow

### 1.1 The porous medium equation

The porous medium equation is given by

$$
\begin{equation*}
\frac{\partial \rho}{\partial t}+\nabla^{2} \rho^{m}=0 \tag{1}
\end{equation*}
$$

Throughout the article, $\rho \geq 0$ should be thought of as a (time-dependent) density function on the whole $N$-dimensional space $\mathbb{R}^{N}$. Here, $\frac{\partial \rho}{\partial t}$ denotes the (partial) derivative w. r. t. time $t \in[0, \infty), \nabla$ denotes the gradient with respect to the spatial variables $x \in \mathbb{R}^{N}, \nabla$. the divergence w. r. t. $x$ and $\nabla^{2}$ the Laplacian w. r. t. $x$. In section 2, we will give a brief derivation of (1) from assumptions on the physics of a gas flow through a porous medium. We restrict our attention to the case where the exponent satisfies $m \geq 1-\frac{1}{N}$ and $m>\frac{N}{N+2}$; the reason for these restrictions will become apparent in the sequel.

The porous medium equation is a parabolic equation, more precisely: a diffusion equation for $\rho$. In case of $m>1$, the diffusion degenerates for $\rho=0$.

This for instance has the effect of preserving a compact support and hence is called "slow diffusion". The case $m>1$ is called fast diffusion. In a weak setting, which will be intruduced in section 5 , the Cauchy problem for (1) is well-posed. Therefore, (1) defines an evolution of densities on $\mathbb{R}^{N}$, in other words: a semi group on the space of densities on $\mathbb{R}^{N}$. We will show that this semi group has the structure of a gradient flow.

### 1.2 Abstract gradient flow

We claim that the porous medium equation can be interpreted as a gradient flow. Let us first introduce the notion of a gradient flow in the generality we need. The mathematical structure required to make sense of a gradient flow is

- a differentiable manifold $\mathcal{M}$,
- a metric tensor $g$ on $\mathcal{M}$, which makes $(\mathcal{M}, g)$ a Riemannian manifold,
- and a function(al) $E$ on $\mathcal{M}$.

We call the dynamical system in $\mathcal{M}$ given by the autonomous differential equation

$$
\begin{equation*}
\frac{d \rho}{d t}=-\operatorname{grad} E_{\mid \rho} \tag{2}
\end{equation*}
$$

the gradient flow of $E$ on $(\mathcal{M}, g)$. Observe that the metric tensor $g$ is a necessary ingredient to the notion. It converts the differential diff $E$ of $E$, which is a cotangent vector field, into the gradient $\operatorname{grad} E$ of $E$, which is a tangent vector field:

$$
\begin{equation*}
g(\operatorname{grad} E, s)=\operatorname{diff} E . s \quad \text { for all vector fields } s \text { on } \mathcal{M} . \tag{3}
\end{equation*}
$$

Hence (2) can be expanded into

$$
\begin{equation*}
g_{\rho}\left(\frac{d \rho}{d t}, s\right)+\operatorname{diff} E_{\mid \rho} \cdot s=0 \quad \text { for all vector fields } s \text { along } \rho \text {. } \tag{4}
\end{equation*}
$$

We point out that the basic property of a gradient flow is that the energy is decreasing along trajectories:

$$
\begin{equation*}
\frac{d}{d t} E(\rho)=\operatorname{diff} E_{\mid \rho} \cdot \frac{d \rho}{d t} \stackrel{(4)}{=}-g_{\rho}\left(\frac{d \rho}{d t}, \frac{d \rho}{d t}\right) \tag{5}
\end{equation*}
$$

### 1.3 Two interpretations of the porous medium equation as gradient flow

It is actually well known that the porous medium equation can be interpreted as a gradient flow. We will introduce this "traditional" gradient flow interpretation in this section. Parallel to this, we will introduce a new gradient flow interpretation. In the following two sections, we will try to convince the reader that our new way of interpreting the porous medium equation is more natural than the traditional way.

The evolution defined by (1) preserves non negativity of $\rho$ and its mass $\int \rho$. In both approaches, the manifold is accordingly given by

$$
\mathcal{M}=\left\{\text { non negative functions } \rho \text { on } \mathbb{R}^{N} \text { with } \int \rho=1\right\} .
$$

We will be deliberately sloppy about the differential structure of the manifold and think of the tangent space as follows

$$
T_{\rho} \mathcal{M}=\left\{\text { functions } s \text { on } \mathbb{R}^{N} \text { with } \int s=0\right\} .
$$

We now come to the metric tensor. Both approaches are based on an identification of the tangent vector space

$$
\begin{equation*}
T_{\rho} \mathcal{M} \cong\left\{\text { functions } p \text { on } \mathbb{R}^{N}\right\} / \sim \tag{6}
\end{equation*}
$$

where the identification is defined via the elliptic equation

$$
\begin{equation*}
-\nabla^{2} p=s \text { for the traditional approach } \tag{7}
\end{equation*}
$$

and

$$
\begin{equation*}
-\nabla \cdot(\rho \nabla p)=s \quad \text { for the new approach. } \tag{8}
\end{equation*}
$$

The " $\sim$ " in (6) is to indicate that we identify $p$ 's which only differ by an additive constant. Now, the metric tensor is defined by

$$
g_{\rho}\left(s_{1}, s_{2}\right)=\int \nabla p_{1} \cdot \nabla p_{2} \quad \text { for the traditional approach }
$$

and

$$
\begin{equation*}
g_{\rho}\left(s_{1}, s_{2}\right)=\int \rho \nabla p_{1} \cdot \nabla p_{2} \quad \text { for the new approach, } \tag{9}
\end{equation*}
$$

where $p_{i}$ is related to $s_{i}$ via (7) resp. (8). For further reference, we notice that this implies

$$
\begin{equation*}
g_{\rho}\left(s_{1}, s_{2}\right)=\int s_{1} p_{2} \quad \text { for both approaches. } \tag{10}
\end{equation*}
$$

Finally the functional: It is given by

$$
E(\rho)=\frac{1}{m+1} \int \rho^{m+1} \quad \text { for the traditional approach }
$$

and

$$
E(\rho)=\left\{\begin{array}{cc}
\frac{1}{m-1} \int \rho^{m} & \text { for } m \neq 1  \tag{11}\\
\int \rho \ln \rho & \text { for } m=1
\end{array}\right\} \quad \text { for the new approach. }
$$

Observe that the differential of the functional is given by

$$
\begin{equation*}
\operatorname{diff} E(\rho) \cdot s=\int \rho^{m} s \quad \text { for the traditional approach } \tag{12}
\end{equation*}
$$

and

$$
\operatorname{diff} E(\rho) \cdot s=\left\{\begin{array}{ll}
\int \frac{m}{m-1} \rho^{m-1} s & \text { for } m \neq 1  \tag{13}\\
\int(\ln \rho+1) s & \text { for } m=1
\end{array}\right\} \quad \text { for the new approach. }
$$

We now have to show that the porous medium equation indeed coincides with the gradient flow of $E$ on $(\mathcal{M}, g)$ for both approaches. First the traditional approach: According to (10) and (12), the identity (4) takes on the form

$$
\int \frac{\partial \rho}{\partial t} p+\int \rho^{m} s=0
$$

where $p$ is related to $s$ via $-\nabla^{2} p=s$. We substitute $s$ accordingly and obtain

$$
\int \frac{\partial \rho}{\partial t} p-\int \rho^{m} \nabla^{2} p=0
$$

and after integration by parts

$$
\int\left(\frac{\partial \rho}{\partial t}-\nabla^{2} \rho^{m}\right) p=0 .
$$

Since $p$ is arbitrary, we recover the porous medium equation.
Now the new approach: According to (10) and (13), the identity (4) takes on the form

$$
\left\{\begin{array}{ll}
\int \frac{\partial \rho}{\partial t} p+\frac{m}{m-1} \int \rho^{m-1} s=0 & \text { for } m \neq 1 \\
\int \frac{\partial \rho}{\partial t} p+\int(\ln \rho+1) s=0 & \text { for } m=1
\end{array}\right\}
$$

where $p$ is related to $s$ via $-\nabla \cdot(\rho \nabla p)=s$. We substitute $s$ accordingly and obtain

$$
\left\{\begin{array}{ll}
\int \frac{\partial \rho}{\partial t} p-\int \frac{m}{m-1} \rho^{m-1} \nabla \cdot(\rho \nabla p)=0 & \text { for } m \neq 1 \\
\int \frac{\partial \rho}{\partial t} p-\int(\ln \rho+1) \nabla \cdot(\rho \nabla p)=0 & \text { for } m=1
\end{array}\right\} .
$$

We obtain after integration by parts

$$
\int\left(\frac{\partial \rho}{\partial t}-\nabla^{2} \rho^{m}\right) p=0 .
$$

Also here, we recover the porous medium equation.
In case of the traditional approach, $g$ does not depend on $\rho$ and therefore is a scalar product on the space of functions $s$ with mean value zero. In fact, it is the homogeneous part of the $H^{-1}$-scalar product. Hence, in the traditional approach, the Riemannian space $(\mathcal{M}, g)$ carries the structure of a convex subspace of a Euclidean space. On the other hand, the new approach is genuinely Riemannian. Hence we must bring forth good reasons for considering the more complicated, new structure. We will attempt to do this in the next two sections.

## 2 A physical argument in favor of the new gradient flow

We give a brief physical derivation of the porous medium equation. The function $\rho$ describes the mass density of a gas in a porous medium. The first assumption is conservation of mass, expressed in the continuity equation

$$
\begin{equation*}
\frac{\partial \rho}{\partial t}+\nabla \cdot(\rho u)=0 \tag{14}
\end{equation*}
$$

where the vector field $u$ on $\mathbb{R}^{N}$ describes the (average) velocity of the gas. The second assumption is Darcy's law

$$
u=-M . \nabla p
$$

where the function $p$ on $\mathbb{R}^{N}$ describes the pressure of the gas and the matrix $M$ describes the mobility of the gas in the porous medium. $M$ depends on the permeability of the medium and the viscosity of the gas. We assume that the permeability is isotropic and homogeneous, so that $K=$ id by an appropriate non-dimensionalization:

$$
\begin{equation*}
u=-\nabla p \tag{15}
\end{equation*}
$$

The third assumption comes from thermodynamics:

$$
\begin{equation*}
p=\frac{\delta E}{\delta \rho} \tag{16}
\end{equation*}
$$

where $E$ denotes the free energy and $\frac{\delta E}{\delta \rho}$ its functional derivative with respect to $\rho$. In case of a free energy of the form

$$
E=\int e(\rho)
$$

where the function $z \mapsto e(z)$ describes how the free energy density $e$ depends on the density $\rho$, (16) reads

$$
\begin{equation*}
p=e^{\prime}(\rho) . \tag{17}
\end{equation*}
$$

Hence (14), (15) and (17) combine to

$$
\begin{equation*}
\frac{\partial \rho}{\partial t}-\nabla^{2} \pi(\rho)=0 \tag{18}
\end{equation*}
$$

where the function $z \mapsto \pi(z)$ describes how the osmotic pressure $\pi$ depends on the density $\rho$ and is related to $z \mapsto e(z)$ via

$$
\begin{equation*}
\pi(z)=z e^{\prime}(z)-e(z) \tag{19}
\end{equation*}
$$

From (19) we see that (18) turns into the porous medium equation (1), that is,

$$
\begin{equation*}
\pi(z)=z^{m} \tag{20}
\end{equation*}
$$

if and only if

$$
e(z)=\left\{\begin{array}{ll}
\frac{1}{m-1} z^{m} & \text { for } m \neq 1  \tag{21}\\
z \ln z & \text { for } m=1
\end{array}\right\} .
$$

Hence, only in the new formulation does $E$ have a physical meaning.
Also the metric tensor $g$ of the new formulation has a physical meaning. For this we observe that the definition (9) of $g$ in the new approach can be reformulated as

$$
g_{\rho}(s, s)=\inf \left\{\int \rho|u|^{2} \left\lvert\, \quad \begin{array}{l}
\text { for all vector fields } u \text { on } \mathbb{R}^{N}  \tag{22}\\
\text { with } s+\nabla \cdot(\rho u)=0
\end{array}\right.\right\} .
$$

Indeed, the minimizer $u$ of the quadratic variational problem in (22) satisfies

$$
\int v \cdot u \text { for all vector fields } v \text { on } \mathbb{R}^{N} \text { with } \nabla \cdot v=0
$$

so that there exists a function $p$ on $\mathbb{R}^{N}$ such that

$$
u=-\nabla p .
$$

We now observe that the quantity $\int \rho|u|^{2}$ in (22) has a physical meaning: It is the rate of dissipation of kinetic energy by friction when the gas moves with velocity $u$ through the pores of the porous medium. Hence $g_{\rho}(s, s)$ measures the minimal rate of dissipation of kinetic energy by friction required to produce the rate of change $s$ of the density $\rho$. This allows for a nice physical interpretation of (5), that is

$$
\frac{d}{d t} E(\rho)=-g_{\rho}\left(\frac{d \rho}{d t}, \frac{d \rho}{d t}\right) .
$$

The right hand side is the rate of change of the free energy, the left hand side is the rate of dissipation of kinetic energy by friction; the dynamics are such that both quantities are equal. In general terms: The merit of the right gradient flow formulation of a dissipative evolution equation is that it separates energetics and kinetics: The energetics endow the state space $\mathcal{M}$ with a functional $E$, the kinetics endow the state space with a (Riemannian) geometry via the metric tensor $g$.

## 3 A mathematical argument in favor of new gradient flow

### 3.1 Self similar solutions and asymptotic behaviour

It is well-known that the long-time asymptotics of the porous medium equation is described by the Barenblatt solution. Let us make this more precise: The porous medium equation allows for a self-similar solution of the form

$$
\rho_{*}(t, x)=\frac{1}{t^{N \alpha}} \hat{\rho}_{*}\left(\frac{x}{t^{\alpha}}\right)
$$

where the profile $\hat{\rho}_{*}$ is given implicitly in the "pressure variable" (for a motivation of this wording see the previous section)

$$
e^{\prime}\left(\hat{\rho}_{*}(y)\right)=\left\{\begin{array}{cccc}
\frac{m}{m-1} \hat{\rho}_{*}(y)^{m-1} & = & \max \left\{\lambda-\alpha \frac{1}{2}|y|^{2}, 0\right\} & \text { for } m>1 \\
\ln \hat{\rho}_{*}(y)+1 & = & \lambda-\alpha \frac{1}{2}|y|^{2} & \text { for } m=1 \\
\frac{m}{m-1} \hat{\rho}_{*}(y)^{m-1} & = & \lambda-\alpha \frac{1}{2}|y|^{2} & \text { for } m<1
\end{array}\right\} .
$$

Here

$$
\alpha=\frac{1}{N(m-1)+2}
$$

and $\lambda$ is such that

$$
\int \hat{\rho}_{*}=1 .
$$

These solutions were discovered by Barenblatt and Prattle [2, 23].
The Barenblatt solution describes the long-time asymptotics of an arbitrary solution $\rho$ in the following sense: Rescale time and space according to

$$
x=t^{\alpha} y \quad \text { and } \quad t=\exp (\tau) .
$$

In terms of density functions, this means: pass from $\rho$ to $\hat{\rho}$ given by

$$
\rho(t, x)=\frac{1}{t^{N \alpha}} \hat{\rho}\left(\ln t, \frac{x}{t^{\alpha}}\right)
$$

Then $\hat{\rho}$ approaches the profile $\hat{\rho}^{*}$ of the Barenblatt solution for large times. In case of $m>1$, Friedman, Kamin and Vazquez (in [12] and [17]) have proved that the profiles converge uniformly

$$
\lim _{\tau \uparrow \infty}\left\|\hat{\rho}-\hat{\rho}_{*}\right\|_{L^{\infty}\left(\boldsymbol{R}^{N}\right)}=0 .
$$

Their proof is based on a $C^{\alpha}$-a priori estimates for the solution of the porous medium equation by Caffarelli and Friedman [5].

### 3.2 A new asymptotic result

Hoping to convince the reader of our new approach, we will derive a new and more quantitative asymptotic result using it. Our arguments are based on a simple Riemannian calculus applied to the infinite dimensional $(\mathcal{M}, g)$. From now on, the notation $g$ and $E$ pertains solely to the new approach, that is, it is defined like in (9) and (11). Next to the metric tensor $g$, which we also denote by $\langle\cdot, \cdot\rangle$, and its induced norm $|\cdot|$, we will need a few notions from Riemannian geometry, like the gradient $\operatorname{grad} F$, the Hessian Hess $F$ of a function $F$ on $\mathcal{M}$, the latter being defined via the covariant derivative, see for instance [22, Section 2.1.3], and the induced distance $d$, see [22, Section 5.3].

The three key ingredients for our asymptotic result are

- $\hat{\rho}$ satisfies

$$
\begin{equation*}
\frac{d \hat{\rho}}{d \tau}=-\operatorname{grad} F_{\mid \hat{\rho}} \tag{23}
\end{equation*}
$$

In words, $\hat{\rho}$ evolves according to the gradient flow on the same Riemannian manifold $(\mathcal{M}, g)$ of an augmented functional $F$ given by

$$
F(\hat{\rho})=E(\hat{\rho})+\alpha M(\hat{\rho})
$$

where $M$ denotes the second moment of the density $\hat{\rho}$

$$
M(\hat{\rho})=\int \frac{1}{2}|y|^{2} \hat{\rho}(y) d y
$$

- $\hat{\rho}_{*}$ satisfies

$$
\begin{equation*}
F(\hat{\rho})-F\left(\hat{\rho}_{*}\right) \geq 0 \quad \text { for all } \hat{\rho} \in \mathcal{M} \tag{24}
\end{equation*}
$$

In words, $\hat{\rho}_{*}$ is a minimizer of $F$ on $\mathcal{M}$. Hence it it is also a stationary point of $F$, that is

$$
\begin{equation*}
0=-\operatorname{grad} F_{\mid \hat{\rho}_{*}} . \tag{25}
\end{equation*}
$$

- $F$ satisfies

$$
\text { Hess } F_{\mid \hat{\rho}} \geq \alpha \text { id } \quad \text { for all } \hat{\rho} \in \mathcal{M}
$$

in the sense of

$$
\begin{equation*}
\left\langle s, \text { Hess } F_{\mid \hat{\rho}} s\right\rangle \geq \alpha|s|^{2} \quad \text { for all } s \in T_{\hat{\rho}} \mathcal{M} \text { and } \hat{\rho} \in \mathcal{M} . \tag{26}
\end{equation*}
$$

In words, $F$ is uniformly strictly convex on $(\mathcal{M}, g)$. This is a consequence of

$$
\begin{equation*}
\text { Hess } E_{\mid \hat{\rho}} \geq 0 \quad \text { and } \quad \text { Hess } M_{\mid \hat{\rho}}=\text { id } \quad \text { for all } \hat{\rho} \in \mathcal{M} \tag{27}
\end{equation*}
$$

We will check (23) and (24) in subsection 3.4; (27) will be established in subsection 4.4. The condition $m \geq 1-\frac{1}{N}$ is the one which ensures that $E$ is convex on $(\mathcal{M}, g)$. The condition $m \geq \frac{N}{N+2}$ ensures that $E\left(\hat{\rho}_{*}\right)$ and $M\left(\hat{\rho}_{*}\right)$ are well-defined and finite.

As we will see in subsection 3.5, (23), (25) and (26) yield by formal but basic Riemannian calculus

$$
\begin{align*}
\frac{d}{d \tau}\left(\exp (2 \alpha \tau)\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}\right) & \leq 0  \tag{28}\\
\frac{d}{d \tau}\left(\exp (2 \alpha \tau)\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)\right) & \leq 0  \tag{29}\\
\frac{d}{d \tau}\left(\exp (2 \alpha \tau) d\left(\hat{\rho}, \hat{\rho}_{*}\right)^{2}\right) & \leq 0 \tag{30}
\end{align*}
$$

We consider these three inequalities the main result of this paper. Observe that (28), (29) and (30) express a single fact in different form. The single fact being: $\hat{\rho}$ converges to $\hat{\rho}_{*}$ with rate $\alpha$. More precisely, $\alpha$ is an exponential rate with respect to $\tau$ or a polynomial rate with respect to $t$. The different forms being: $\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|$ in (28) measures how far $\hat{\rho}$ is from being a stationary point of $F, F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)$ in (29) is measuring how far $\hat{\rho}$ is from being a minimizer of $F$ and finally $d\left(\hat{\rho}, \hat{\rho}_{*}\right)$ in (30) is measuring how far $\hat{\rho}$ is from $\hat{\rho}_{*}$.

In subsection 3.4, we will identify $\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}$ as the functional

$$
\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}=\int \hat{\rho}|\nabla p|^{2} \quad \text { where } \quad p(y)=e^{\prime}(\hat{\rho}(y))+\alpha \frac{1}{2}|y|^{2}
$$

and $e$ is the energy density given in (21). In subsection 4.3 , we will identify the induced metric $d$ with the Wasserstein metric, that is

$$
d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}=\inf _{\hat{\rho}_{1}=\Phi \# \hat{\rho}_{0}} \int \hat{\rho}_{0}|\operatorname{id}-\Phi|^{2}
$$

where $\Phi \# \hat{\rho}_{0}$ denotes the push forward of the density $\hat{\rho}_{0}$ under the transformation $\Phi$ of $\mathbb{R}^{N}$. By carefully mimicking the formal Riemannian calculus from subsection 3.5, we will make the above results rigorous in Theorem 1 in section 5. A relationship, not in the above concise form though, between the porous medium equation, its self similar solution and the Wasserstein metric was discovered by the author in [21].

In the linear case $m=1$, above results are known to the Fokker-Planck community in a different form. In this case,

$$
\begin{aligned}
\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} & =\int \hat{\rho}|\nabla p|^{2} \\
& =\int \hat{\rho}\left|\frac{1}{\hat{\rho}} \nabla \hat{\rho}+\alpha y\right|^{2} \\
& =\int \frac{1}{\hat{\rho}}|\nabla \hat{\rho}|^{2}-2 \alpha N \int \hat{\rho}+\alpha^{2} \int \hat{\rho}|y|^{2} \\
& =\int \frac{1}{\hat{\rho}}|\nabla \hat{\rho}|^{2}-2 \alpha N+2 \alpha^{2} M(\hat{\rho}) .
\end{aligned}
$$

In particular, $0=\left|\operatorname{grad} F_{\mid \hat{\rho}_{*}}\right|^{2}=\int \frac{1}{\hat{\rho}_{*}}\left|\nabla \hat{\rho}_{*}\right|^{2}-2 \alpha N+\alpha^{2} M\left(\hat{\rho}_{*}\right)$, so that

$$
\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}=\int \frac{1}{\hat{\rho}}|\nabla \hat{\rho}|^{2}-\int \frac{1}{\hat{\rho}_{*}}\left|\nabla \hat{\rho}_{*}\right|^{2} \quad \text { if } \quad M(\hat{\rho})=M\left(\hat{\rho}_{*}\right) .
$$

The quantity $\int \frac{1}{\hat{\rho}}|\nabla \hat{\rho}|^{2}$ is called the "Fisher information functional". Also in this case

$$
F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)=\int \hat{\rho} \ln \hat{\rho}-\int \hat{\rho}_{*} \ln \hat{\rho}_{*} \quad \text { if } \quad M(\hat{\rho})=M\left(\hat{\rho}_{*}\right)
$$

and the quantity $\int \hat{\rho} \ln \hat{\rho}$ is called the "entropy functional". The decay of the Fisher information functional and the entropy functional expressed in (28) resp. (29) for $m=1$ seems to be due to McKean [19] and Toscani [7]. Recently and independently of our work, these ideas for (28) resp. (29) have been
extended to the case $m \neq 1$ by Carrillo \& Toscani [8] (for $m>1$ ) and Dolbeault \& del Pino [10] (for $m<1$ ). Forerunners in this Liapunov-functional based approach were also Newman [20] and Ralston [25]. The novelty of our above results is their formulation, interpretation and proof in framework of Riemannian geometry, which make the approach more transparent and the calculations seem less arbitrary.

### 3.3 The asymptotic result expressed in a more traditional framework

Convergence with rate $\alpha$ in a more traditional way can be derived from (29) with help of

- the inequalities

$$
F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\left\{\begin{array}{ll}
\geq & H\left(\hat{\rho}, \hat{\rho}_{*}\right)  \tag{31}\\
=H\left(\hat{\rho}, \hat{\rho}_{*}\right) & \text { for } m>1 \\
=
\end{array}\right\},
$$

where

$$
H\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)=\int\left\{e\left(\hat{\rho}_{1}\right)-e\left(\hat{\rho}_{0}\right)-e^{\prime}\left(\hat{\rho}_{0}\right)\left(\hat{\rho}_{1}-\hat{\rho}_{0}\right)\right\} \geq 0
$$

Here the $e$ is the energy density, see (21), and in the case $m<1$, we set $H\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)=+\infty$ if $\hat{\rho}_{0}$ vanishes on a set of positive measure.

- the estimate for $m \leq 2$

$$
\begin{equation*}
\int\left|\hat{\rho}_{1}-\hat{\rho}_{0}\right| \leq C\left(\int \hat{\rho}_{0}^{2-m}\right)^{\frac{1}{2}} H\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)^{\frac{1}{2}}, \tag{32}
\end{equation*}
$$

where $C$ is a constant which only depends on $m$.
It is conceivable that convergence of rate $\alpha$ in stronger traditional norms can be derived from (28), (29) and (30). But this is not the focus of this paper.

The inequality (31) will be established in subsection 3.4 , the non negativity of $H$ follows immediately from the convexity of $e$. In the case of $m=1$, we have

$$
e\left(z_{1}\right)-e\left(z_{0}\right)-e^{\prime}\left(z_{0}\right)\left(z_{1}-z_{0}\right)=\frac{z}{z_{0}} \ln \frac{z}{z_{0}} z_{0}-\left(z_{1}-z_{0}\right),
$$

so that

$$
\begin{equation*}
H\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)=\int \frac{\hat{\rho}_{1}}{\hat{\rho}_{0}} \ln \frac{\hat{\rho}_{1}}{\hat{\rho}_{0}} \hat{\rho}_{0} . \tag{33}
\end{equation*}
$$

Therefore, $H\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)$ is also called the relative entropy of $\hat{\rho}_{1}$ w. r. t. $\hat{\rho}_{0}$. The estimate (32) is known to the Fokker-Planck community under the name of Csiszar-Kullback inequality [18].

Let us now establish (32). Since $m \leq 2$ implies

$$
e^{\prime \prime}(w)=m w^{m-2} \geq m \text { for } w \in[0,1]
$$

we have

$$
\begin{align*}
& \frac{1}{m-1} w^{m}-\frac{1}{m-1}-\frac{m}{m-1} w^{m-1}(w-1) \\
& =e(w)-e(1)-e^{\prime}(1)(w-1) \\
& \geq \frac{1}{2} \inf _{(0,1)} e^{\prime \prime}(w-1)^{2} \\
& =\frac{m}{2}(w-1)^{2} \quad \text { for all } w \in[0,1] . \tag{34}
\end{align*}
$$

We observe that since

$$
\int\left(\hat{\rho}_{1}-\hat{\rho}_{0}\right)=0
$$

we have

$$
\int\left|\hat{\rho}_{1}-\hat{\rho}_{0}\right|=2 \int_{\left\{\hat{\rho}_{1}<\hat{\rho}_{0}\right\}}\left|\hat{\rho}_{1}-\hat{\rho}_{0}\right| .
$$

On the other hand, setting

$$
u=\left\{\begin{array}{cc}
\frac{\hat{\rho}_{1}}{\hat{\rho}_{0}} & \text { if } \hat{\rho}_{1}<\hat{\rho}_{0} \\
1 & \text { else }
\end{array}\right\} \in[0,1]
$$

we have

$$
\begin{aligned}
& \int_{\left\{\hat{\rho}_{1}<\hat{\rho}_{0}\right\}}\left|\hat{\rho}_{1}-\hat{\rho}_{0}\right| \\
& \quad=\int \hat{\rho}_{0}|u-1| \\
& \quad \leq\left(\int \hat{\rho}_{0}^{2-m} \int \hat{\rho}_{0}^{m}(u-1)^{2}\right)^{\frac{1}{2}}
\end{aligned}
$$

$$
\begin{aligned}
& \stackrel{(34)}{\leq}\left(\int \hat{\rho}_{0}^{2-m} \frac{2}{m} \int \hat{\rho}_{0}^{m}\left\{\frac{1}{m-1} u^{m}-\frac{1}{m-1}-\frac{m}{m-1} u^{m-1}(u-1)\right\}\right)^{\frac{1}{2}} \\
& =\left(\int \hat{\rho}_{0}^{2-m} \frac{2}{m} \int_{\left\{\hat{\rho}_{1}<\hat{\rho}_{0}\right\}}\left\{\frac{1}{m-1} \hat{\rho}_{1}^{m}-\frac{1}{m-1} \hat{\rho}_{0}^{m}-\frac{m}{m-1} \hat{\rho}_{0}^{m-1}\left(\hat{\rho}_{0}-\hat{\rho}_{1}\right)\right\}\right)^{\frac{1}{2}} .
\end{aligned}
$$

### 3.4 Verification of key ingredients to asymptotic result

Let us now check (23). It is left to the reader to verify that $\hat{\rho}$ satisfies the equation

$$
\begin{equation*}
\frac{\partial \hat{\rho}}{\partial \tau}-\nabla_{y}^{2} \hat{\rho}^{m}-\alpha \nabla_{y} \cdot(\hat{\rho} y)=0 \tag{35}
\end{equation*}
$$

¿From now on, we drop the subscript $y$. We observe that the differential of $F$ is given by

$$
\operatorname{diff} F(\hat{\rho}) \cdot s=\left\{\begin{array}{ll}
\int\left(\frac{m}{m-1} \hat{\rho}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right) s & \text { for } m \neq 1 \\
\int\left(\ln \hat{\rho}+1+\alpha \frac{1}{2}|y|^{2}\right) s & \text { for } m=1
\end{array}\right\} .
$$

According to this and (10), the identity (4) takes on the form

$$
\begin{array}{ll}
\int \frac{\partial \hat{\rho}}{\partial \tau} p+\int\left(\frac{m}{m-1} \hat{\rho}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right) s=0 & \text { for } m \neq 1 \\
\int \frac{\partial \hat{\rho}}{\partial \tau} p+\int\left(\ln \hat{\rho}+1+\alpha \frac{1}{2}|y|^{2}\right) s=0 & \text { for } m=1,
\end{array}
$$

where $p$ is related to $s$ via $-\nabla \cdot(\hat{\rho} \nabla p)=s$. We substitute $s$ accordingly and obtain after an integration by part

$$
\begin{array}{ll}
\int\left\{\frac{\partial \hat{\rho}}{\partial \tau}-\nabla \cdot\left[\hat{\rho} \nabla\left(\frac{m}{m-1} \hat{\rho}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right)\right]\right\} p=0 & \text { for } m \neq 1, \\
\int\left\{\frac{\partial \hat{\rho}}{\partial \tau}-\nabla \cdot\left[\hat{\rho} \nabla\left(\ln \hat{\rho}+1+\alpha \frac{1}{2}|y|^{2}\right)\right]\right\} p=0 & \text { for } m=1 .
\end{array}
$$

Hence (4) can be rewritten as

$$
\begin{aligned}
& \frac{\partial \hat{\rho}}{\partial \tau}-\nabla \cdot\left[\hat{\rho} \nabla\left(\frac{m}{m-1} \hat{\rho}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right)\right]=0 \\
& \text { for } m \neq 1 \\
& \frac{\partial \hat{\rho}}{\partial \tau}-\nabla \cdot\left[\hat{\rho} \nabla\left(\ln \hat{\rho}+1+\alpha \frac{1}{2}|y|^{2}\right)\right]=0 \text { for } m=1
\end{aligned}
$$

which turns into (35).

Let us now check that in the notation of (31),

$$
F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\left\{\begin{array}{ll}
\geq H\left(\hat{\rho}, \hat{\rho}_{*}\right) & \text { for } m>1  \tag{36}\\
=H\left(\hat{\rho}, \hat{\rho}_{*}\right) & \text { for } m \leq 1
\end{array}\right\}
$$

This validates both (24) and (31). In order to show (36) in case of $m \neq 1$, we observe that by definition of $H\left(\hat{\rho}, \hat{\rho}_{*}\right)$

$$
E(\hat{\rho})=E\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right)+\int \frac{m}{m-1} \hat{\rho}_{*}^{m-1}\left(\hat{\rho}-\hat{\rho}_{*}\right),
$$

so that by definition of $F$,

$$
F(\hat{\rho})=F\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right)+\int\left(\frac{m}{m-1} \hat{\rho}_{*}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right)\left(\hat{\rho}-\hat{\rho}_{*}\right) .
$$

In case of $m<1$, we have by definition of $\hat{\rho}_{*}$

$$
\frac{m}{m-1} \hat{\rho}_{*}^{m-1}+\alpha \frac{1}{2}|y|^{2}=\lambda,
$$

so that we obtain

$$
F(\hat{\rho})=F\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right)+\lambda \int\left(\hat{\rho}-\hat{\rho}_{*}\right)=F\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right) .
$$

In case of $m>1$, we have by definition of $\hat{\rho}_{*}$,

$$
\begin{equation*}
\left(\frac{m}{m-1} \hat{\rho}_{*}^{m-1}+\alpha \frac{1}{2}|y|^{2}\right)\left(\hat{\rho}-\hat{\rho}_{*}\right) \geq \lambda\left(\hat{\rho}-\hat{\rho}_{*}\right) \quad \text { for all } y \in \mathbb{R}^{N} . \tag{37}
\end{equation*}
$$

Indeed, if $y$ is such that $\lambda-\alpha \frac{1}{2}|y|^{2} \geq 0$ then $\frac{m}{m-1} \hat{\rho}_{*}^{m-1}=\lambda-\alpha \frac{1}{2}|y|^{2}$ and the inequality (37) turns into an equality. On the other hand, if $y$ is such that $\lambda-\alpha \frac{1}{2}|y|^{2} \leq 0, \hat{\rho}_{*}=0$ and the above inequality turns into $\alpha \frac{1}{2}|y|^{2} \hat{\rho} \geq \lambda \hat{\rho}$, which is true since $\hat{\rho} \geq 0$. Hence we obtain in this case only an inequality

$$
F(\hat{\rho}) \geq F\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right)+\lambda \int\left(\hat{\rho}-\hat{\rho}_{*}\right)=F\left(\hat{\rho}_{*}\right)+H\left(\hat{\rho}, \hat{\rho}_{*}\right) .
$$

The identity (36) in case of $m=1$ is also quite obvious. From definition of $F$ and $\hat{\rho}_{*}$ we obtain

$$
F(\hat{\rho})=\int\left(\ln \hat{\rho}+\alpha \frac{1}{2}|y|^{2}\right) \hat{\rho}=\int\left(\ln \hat{\rho}+\lambda-\ln \hat{\rho}_{*}\right) \hat{\rho} \stackrel{(33)}{=} H\left(\hat{\rho}, \hat{\rho}_{*}\right)+\lambda .
$$

In particular $F\left(\hat{\rho}_{*}\right)=\lambda$, so that

$$
F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)=H\left(\hat{\rho}, \hat{\rho}_{*}\right) .
$$

As announced, we will now argue that

$$
\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}=\int \hat{\rho}|\nabla p|^{2} \quad \text { where } \quad p(y)=e^{\prime}(\hat{\rho}(y))+\alpha \frac{1}{2}|y|^{2} .
$$

Indeed, we have by the abstract definition (3) of the gradient

$$
\frac{1}{2} g_{\hat{\rho}}\left(\operatorname{grad} F_{\mid \hat{\rho}}, \operatorname{grad} F_{\mid \hat{\rho}}\right)=\sup _{s \in T_{\hat{\rho}} \mathcal{M}}\left\{d F_{\mid \hat{\rho} \cdot} \cdot s-\frac{1}{2} g_{\hat{\rho}}(s, s)\right\} .
$$

By definition of our functional $F$,

$$
d F_{\mid \hat{\rho}} . s=\int p s \quad \text { with } p \text { as above. }
$$

By definition of our inner product

$$
\int p s-\frac{1}{2} g_{\hat{\rho}}(s, s)=\int \hat{\rho} \nabla p \cdot \nabla q-\int \hat{\rho} \frac{1}{2}|\nabla q|^{2}
$$

if $s \in T_{\hat{\rho}} \mathcal{M}$ and the function $q$ on $\mathbb{R}^{N}$ are related by

$$
-\nabla \cdot(\hat{\rho} \nabla q)=s
$$

Hence

$$
\begin{aligned}
\frac{1}{2} g_{\hat{\rho}}\left(\operatorname{grad} F_{\hat{\rho}}, \operatorname{grad} F_{\mid \hat{\rho}}\right) & =\sup _{\text {function } p \text { on } R^{N}}\left\{\int \hat{\rho} \nabla p \cdot \nabla q-\int \hat{\rho} \frac{1}{2}|\nabla q|^{2}\right\} \\
& =\int \hat{\rho} \frac{1}{2}|\nabla p|^{2}
\end{aligned}
$$

### 3.5 Derivation of asymptotic result by formal Riemannian calculus

Let us now show how (23), (25) and (26) imply (28), (29) and (30) by formal Riemannian calculus. For this, we forget about where our structure $(\mathcal{M}, g)$
and $F$ came from and work exclusively within the abstract framework. The derivation of (28) is easiest:

$$
\begin{align*}
\frac{d}{d \tau}\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} & =2\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \frac{D}{D \tau} \operatorname{grad} F_{\mid \hat{\rho}}\right\rangle \\
& =2\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \operatorname{Hess} F_{\mid \hat{\rho}} \frac{d}{d \tau} \rho\right\rangle \\
& \stackrel{(23)}{=}-2\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \operatorname{Hess} F_{\mid \hat{\rho}} \operatorname{grad} F_{\mid \hat{\rho}}\right\rangle \\
& \stackrel{(26)}{\leq}-2 \alpha\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} . \tag{38}
\end{align*}
$$

Here $\frac{D}{D \tau}$ denotes the covariant derivative along the curve $\hat{\rho}$. The first equality comes from the fundamental property of the covariant derivative [22, Section 2.1.2]; the second equality follows from the definition of the Hessian [22, Section 2.1.3].

We now tackle (29) and (30). There are different ways to derive (29) and (30) from (23), (25) and (26) by Riemannian calculus. We choose the one we are able to make rigorous in section 5 . We need the following auxiliary result. We recall the definition of the induced metric $d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}$ as the infimum of the energy (modulo a factor 2) $\int_{0}^{1}\left|\frac{d}{d \sigma}\right|^{2} d \sigma$ over all curves $[0,1] \ni \sigma \mapsto \tilde{\hat{\rho}}(\sigma) \in \mathcal{M}$ which connect $\hat{\rho}_{0}$ to $\hat{\rho}_{1}$ :

$$
\begin{aligned}
d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}=\left\{\left.\int_{0}^{1}\left|\frac{d \tilde{\hat{\rho}}}{d \sigma}\right|^{2} d \sigma \right\rvert\,\right. & {[0,1] \ni \sigma \mapsto \tilde{\hat{\rho}}(\sigma) \in \mathcal{M} } \\
& \text { with } \left.\tilde{\hat{\rho}}(0)=\hat{\rho}_{0}, \tilde{\hat{\rho}}(1)=\hat{\rho}_{1} \quad\right\}
\end{aligned}
$$

Let $[0,1] \ni \sigma \mapsto \tilde{\hat{\rho}}(\sigma)$ denote a curve of least energy between $\hat{\rho}_{0}$ and $\hat{\rho}_{1}$, that is,

$$
\begin{equation*}
d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}=\int_{0}^{1}\left|\frac{d \tilde{\hat{\rho}}}{d \sigma}\right|^{2} d \sigma \tag{39}
\end{equation*}
$$

In particular, $[0,1] \ni \sigma \mapsto \tilde{\hat{\rho}}(\sigma)$ is a geodesic, that is

$$
\begin{equation*}
\frac{D}{d \sigma} \frac{d \tilde{\hat{\rho}}}{d \sigma}=0 \tag{40}
\end{equation*}
$$

which implies

$$
\begin{equation*}
\frac{d}{d \sigma}\left|\frac{d \tilde{\hat{\rho}}}{d \sigma}\right|^{2}=2\left\langle\frac{d \hat{\rho}}{d \sigma}, \frac{D}{d \sigma} \frac{d \tilde{\hat{\rho}}}{d \sigma}\right\rangle=0 . \tag{41}
\end{equation*}
$$

The auxiliary result we claim is

$$
\begin{equation*}
F\left(\hat{\rho}_{1}\right)-F\left(\hat{\rho}_{0}\right) \geq\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma}{ }_{\mid \sigma=0}, \operatorname{grad} F_{\mid \hat{\rho}_{0}}\right\rangle+\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} . \tag{42}
\end{equation*}
$$

Indeed, this is a consequence of

$$
\frac{d}{d \sigma} F(\tilde{\hat{\rho}})=\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma}, \operatorname{grad} F_{\mid \tilde{\hat{\rho}}}\right\rangle
$$

and

$$
\left.\begin{aligned}
\frac{d^{2}}{d \sigma^{2}} F(\tilde{\hat{\rho}}) & =\left\langle\frac{D}{d \sigma} \frac{d \tilde{\hat{\rho}}}{d \sigma}, \operatorname{grad} F_{\mid \tilde{\hat{\rho}}}\right\rangle+\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma}, \frac{D}{d \sigma} \operatorname{grad} F_{\mid \tilde{\hat{\rho}}}\right\rangle \\
& \stackrel{(40)}{=}
\end{aligned}\left\langle\frac{\left.d \frac{\tilde{\hat{\rho}}}{d \sigma}, \operatorname{Hess} F_{\mid \tilde{\hat{\rho}}} \frac{d \tilde{\hat{\rho}}}{d \sigma}\right\rangle}{} \quad \stackrel{(26)}{\geq} \quad \alpha\right| \frac{d \tilde{\hat{\rho}}}{d \sigma}\right|^{2} .
$$

By symmetry, we also have

$$
\begin{equation*}
F\left(\hat{\rho}_{0}\right)-F\left(\hat{\rho}_{1}\right) \geq-\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma_{\mid \sigma=1}}, \operatorname{grad} F_{\mid \hat{\rho}_{1}}\right\rangle+\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} . \tag{43}
\end{equation*}
$$

Adding (42) and (43) yields

$$
\begin{equation*}
\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma}{ }_{\mid \sigma=1}, \operatorname{grad} F_{\mid \hat{\rho}_{1}}\right\rangle-\left\langle\left.\frac{d \tilde{\hat{\rho}}}{d \sigma}\right|_{\mid \sigma=0}, \operatorname{grad} F_{\mid \hat{\rho}_{0}}\right\rangle \geq \alpha d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} . \tag{44}
\end{equation*}
$$

For later reference, we note that (42) also implies

$$
\begin{aligned}
& F\left(\rho_{1}\right)-F\left(\rho_{0}\right) \geq-\left|\frac{d \tilde{\hat{\rho}}^{d \sigma}}{d \sigma=0}\right|\left|\operatorname{grad} F_{\left|\hat{\rho}_{0}\right|}\right| \\
&\left(\left.\begin{array}{l}
(39),(41) \\
=
\end{array} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right) \right\rvert\, \operatorname{grad} F_{\left|\hat{\rho}_{0}\right|},\right.
\end{aligned}
$$

hence by symmetry,

$$
\begin{equation*}
\left|F\left(\rho_{1}\right)-F\left(\rho_{0}\right)\right| \leq d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right) \max \left\{\left|\operatorname{grad} F_{\mid \hat{\rho}_{0}}\right|,\left|\operatorname{grad} F_{\mid \hat{\rho}_{1}}\right|\right\} . \tag{45}
\end{equation*}
$$

We now derive (30) by formal Riemannian calculus. Because of (25), $\hat{\rho}_{0}(\tau)=$ $\hat{\rho}_{*}$ defines a (stationary) solution of (23). Hence it suffices to show the contraction property

$$
\begin{equation*}
\frac{d^{+}}{d \tau} d\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)^{2} \leq 2 \alpha d\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)^{2} \tag{46}
\end{equation*}
$$

for two solutions $\hat{\rho}_{i}$ of (23). Here, $\frac{d^{+}}{d \tau}$ denotes

$$
\frac{d^{+}}{d \tau}{\mid \tau_{0}}^{f}=\limsup _{\tau \downarrow \tau_{0}} \frac{f(\tau)-f\left(\tau_{0}\right)}{\tau-\tau_{0}} .
$$

We fix a $\tau_{0}$. For any $\tau$, let $[0,1] \ni \sigma \mapsto \tilde{\hat{\rho}}(\tau, \sigma) \in \mathcal{M}$ be a curve between $\tilde{\hat{\rho}}(\tau, 0)=\hat{\rho}_{0}(\tau)$ and $\tilde{\hat{\rho}}(\tau, 1)=\hat{\rho}_{1}(\tau)$. We may arrange for that it is the curve of least energy for $\tau=\tau_{0}$ and depends smoothly on $\tau$, so that

$$
d\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)^{2}\left\{\begin{array}{ll}
=\int_{0}^{1}\left|\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}\right|^{2} d \sigma & \text { for } \tau=\tau_{0}  \tag{47}\\
\leq \int_{0}^{1}\left|\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}\right|^{2} d \sigma & \text { for any } \tau
\end{array}\right\}
$$

Hence for $\tau=\tau_{0}$,

$$
\begin{aligned}
& {\frac{d^{+}}{d \tau}}_{\mid \tau_{0}} d\left(\hat{\rho}_{1}, \hat{\rho}_{0}\right)^{2} \stackrel{(47)}{\leq} \frac{d}{d \tau}{\mid \tau_{0}}^{\int_{0}^{1}\left|\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}\right|^{2} d \sigma} \\
& =2 \int_{0}^{1}\left\langle\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}, \frac{D}{\partial \tau}{\mid \tau_{0}}_{\partial \sigma} \frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}\right\rangle d \sigma \\
& =2 \int_{0}^{1}\left\langle\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}, \frac{D}{\partial \sigma} \frac{\partial \tilde{\hat{\rho}}}{\partial \tau}{ }_{\mid \tau_{0}}\right\rangle d \sigma \\
& =2 \int_{0}^{1}\left\{\frac{d}{d \sigma}\left\langle\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}, \frac{\partial \tilde{\hat{\rho}}}{\partial \tau}{ }_{\mid \tau_{0}}\right\rangle-\left\langle\frac{D}{\partial \sigma} \frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}, \frac{\partial \tilde{\hat{\rho}}}{\partial \tau}{\mid \tau_{0}}\right\rangle\right\} d \sigma \\
& \stackrel{(40)}{=} 2 \int_{0}^{1} \frac{d}{d \sigma}\left\langle\frac{\partial \tilde{\hat{\rho}}}{\partial \sigma}, \frac{\partial \tilde{\hat{\rho}}}{\partial \tau}{ }_{\mid \tau_{0}}\right\rangle d \sigma \\
& =2\left(\left\langle\frac{d \tilde{\hat{\rho}}^{d \sigma}}{\mid \sigma=1}, \frac{d \hat{\rho}_{1}}{d \tau}\right\rangle-\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma_{\mid \sigma=0}}, \frac{d \hat{\rho}_{0}}{d \tau}\right\rangle\right) \\
& \stackrel{(23)}{=}-2\left(\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma_{\mid \sigma=1}}, \operatorname{grad} F_{\mid \hat{\rho}_{1}}\right\rangle-\left\langle\frac{d \tilde{\hat{\rho}}}{d \sigma}{ }_{\mid \sigma=0}, \operatorname{grad} F_{\mid \hat{\rho}_{0}}\right\rangle\right) \\
& \stackrel{(44)}{\leq}-2 \alpha d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2},
\end{aligned}
$$

which establishes (46).
We finally show how to get (29) by formal Riemannian calculus. We need the ingredient that

$$
\begin{equation*}
\lim _{\tau \uparrow \infty}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)=0, \tag{48}
\end{equation*}
$$

which in a finite dimensional context would immediately follow from (30) in the weakened form of

$$
\begin{equation*}
\lim _{\tau \uparrow \infty} d\left(\hat{\rho}, \hat{\rho}_{*}\right)=0, \tag{49}
\end{equation*}
$$

In our infinite dimensional context, we obtain (48) from (49) and from (28) in the weakened form of

$$
\begin{equation*}
\lim _{\tau \uparrow \infty}\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|=0 \tag{50}
\end{equation*}
$$

via the interpolation inequality

$$
\left|F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right| \leq\left|\operatorname{grad} F_{\mid \hat{\rho}}\right| d\left(\hat{\rho}, \hat{\rho}_{*}\right) \quad \text { for all } \hat{\rho} \in \mathcal{M}
$$

which we obtain from (45), using $\operatorname{grad} F_{\mid \hat{\rho}_{*}} \stackrel{(25)}{=} 0$.
We now derive (29) in form of

$$
\frac{d}{d \tau}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right) \leq-2 \alpha\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)
$$

We first observe that

$$
\begin{equation*}
\frac{d}{d \tau}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)=\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \frac{d \hat{\rho}}{d \tau}\right\rangle \stackrel{(23)}{=}-\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} . \tag{51}
\end{equation*}
$$

Hence we get

$$
\begin{aligned}
\frac{d}{d \tau}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right) & \stackrel{(51)}{=}-\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} \\
& \stackrel{(50)}{=} \int_{\tau}^{\infty} \frac{d}{d \tau}\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} d \tau \\
& \stackrel{(38)}{\leq}-2 \alpha \int_{\tau}^{\infty}\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2} d \tau \\
& \stackrel{(51)}{=} 2 \alpha \int_{\tau}^{\infty} \frac{d}{d \tau}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right) d \tau \\
& \stackrel{(48)}{=}-2 \alpha\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right) .
\end{aligned}
$$

## 4 The geometry of $(\mathcal{M}, g)$

The best way to understand the geometry of $(\mathcal{M}, g)$ is: It is induced by a flat Riemannian space $\left(\mathcal{M}^{*}, g^{*}\right)$ via a submersion $\Pi$. The intuition behind this is the following: The porous medium equation describes the diffusion of gas particles through a porous medium. $\mathcal{M}$ describes the state via the particle densities $\rho$ - an Eulerian description. $\mathcal{M}^{*}$ will describe the state via the particle coordinates or flow map $\Phi$ - a Lagrangian description.

### 4.1 The isometric submersion $\Pi$

We fix a $\rho_{0} \in \mathcal{M}$. We start by introducing the manifold $\mathcal{M}^{*}$ and the submersion $\Pi: \mathcal{M}^{*} \rightarrow \mathcal{M}$. The manifold is the set of all diffeomorphisms of $\mathbb{R}^{N}$ :

$$
\mathcal{M}^{*}=\left\{\text { diffeomorphisms } \Phi \text { of } \mathbb{R}^{N}\right\} .
$$

And $\rho=\Pi(\Phi)$ is given by the push forward of the reference density $\rho_{0}$ under the map $\Phi$. More precisely,

$$
\begin{equation*}
\int \rho \zeta=\int \rho_{0} \zeta \circ \Phi \text { for all functions } \zeta \text { on } \mathbb{R}^{N} \text {. } \tag{52}
\end{equation*}
$$

We also use the notation

$$
\rho=\Phi \# \rho_{0} .
$$

We now endow $\mathcal{M}^{*}$ with a metric tensor $g^{*}$. Again, we will be sloppy about the differential structure of $\mathcal{M}^{*}$ and think of the tangent space as the space of all vector fields on $\mathbb{R}^{N}$

$$
T_{\Phi} \mathcal{M}^{*}=\left\{\text { vector fields } v \text { on } \mathbb{R}^{N}\right\}
$$

which we endow with the scalar product

$$
g_{\Phi}^{*}\left(v_{1}, v_{2}\right)=\int \rho_{0} v_{1} \cdot v_{2} .
$$

In other words, $\left(\mathcal{M}^{*}, g^{*}\right)$ carries the geometry of the ambient $L^{2}$-space with weight $\rho_{0}$. In particular $\left(\mathcal{M}^{*}, g^{*}\right)$ is flat.

We now argue that $\Pi$ is an isometric submersion from $\left(\mathcal{M}^{*}, g^{*}\right)$ into $(\mathcal{M}, g)$; for the notion of isometric submersion, see for instance [22, Chapter 1.1]. We
have to show: For any $\Phi \in \mathcal{M}$, the tangential

$$
\begin{equation*}
T_{\Phi} \Pi: T_{\Phi} \mathcal{M}^{*} \rightarrow T_{\rho} \mathcal{M} \tag{53}
\end{equation*}
$$

of $\Pi$ at $\Phi$ has the property

$$
\begin{equation*}
g_{\rho}(s, s)=\inf _{T_{\Phi} \Pi . v=s} g_{\Phi}(v, v) \quad \text { for all } s \in T_{\rho} \mathcal{M}, \tag{54}
\end{equation*}
$$

where $\rho=\Pi(\Phi)$. We observe that (54) implies that $T_{\Phi} \Pi$ is an isometry when restricted to the orthogonal complement $\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ of its $\operatorname{kernel} \operatorname{ker} T_{\Phi} \Pi \subset$ $T_{\Phi} \mathcal{M}^{*}$. In the language of differential geometry: A tangent vector in $\operatorname{ker} T_{\Phi} \Pi$ is called 'vertical', a tangent vector in $\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ is called 'horizontal'.

In order to establish property (54), we give a characterization of the tangential $T_{\Phi} \Pi$ and the spaces $\operatorname{ker} T_{\Phi} \Pi$ and $\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$. It is convenient to do so in terms of the identification (8) of tangent vectors $s \in T_{\rho} \mathcal{M}$ with potentials $p$ and the following identification of tangent vectors $v \in T_{\Phi} \mathcal{M}^{*}$ with velocity fields $u$ :

$$
\begin{equation*}
T_{\Phi} \mathcal{M}^{*} \cong\left\{\text { vector fields } u \text { on } \mathbb{R}^{N}\right\} \tag{55}
\end{equation*}
$$

via

$$
v=u \circ \Phi .
$$

We observe that in terms of $u$, the metric tensor $g^{*}$ assumes the form

$$
\begin{equation*}
g_{\Phi}^{*}\left(v_{1}, v_{2}\right)=\int \rho u_{1} \cdot u_{2}, \quad \text { where } \rho=\Pi(\Phi) . \tag{56}
\end{equation*}
$$

We now show that in terms of $p$ and $u$,

- $T_{\Phi} \Pi . u$ is the function $p$ on $\mathbb{R}^{N}$ (determined up to additive constants) which solves

$$
\begin{equation*}
-\nabla \cdot(\rho \nabla p)=-\nabla \cdot(\rho u) . \tag{57}
\end{equation*}
$$

- $u \in \operatorname{ker} T_{\Phi} \Pi$ if and only if the vector field $u$ on $\mathbb{R}^{N}$ satisfies

$$
\begin{equation*}
\nabla \cdot(\rho u)=0 . \tag{58}
\end{equation*}
$$

- $u \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ if and only if the vector field $u$ on $\mathbb{R}^{N}$ satisfies

$$
\begin{equation*}
u=\nabla p \quad \text { for some function } p \text { on } \mathbb{R}^{N} . \tag{59}
\end{equation*}
$$

The line (58) follows immediately from (57). The line (59) follows from (57) easily: Because of $(56)$ and (58), $u \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ means

$$
\int w \cdot u=0 \quad \text { for all vector fields } w \text { on } \mathbb{R}^{N} \text { with } \nabla \cdot w=0
$$

which implies (59) by elementary vector calculus.
It remains to establish (57), which we will do in the variational form

$$
\begin{equation*}
\int \rho \nabla p \cdot \nabla \zeta=\int \rho u \cdot \nabla \zeta \text { for all functions } \zeta \text { on } \mathbb{R}^{N} \tag{60}
\end{equation*}
$$

Obviously,

$$
\begin{equation*}
\frac{\partial \tilde{\Phi}}{\partial \sigma}(\sigma)=u \circ \tilde{\Phi}(\sigma), \quad \tilde{\Phi}(0)=\Phi \tag{61}
\end{equation*}
$$

defines a curve $\sigma \mapsto \tilde{\Phi}(\sigma) \in \mathcal{M}^{*}$ which for $\sigma=0$ passes through $\Phi$ and has tangent $u$ there. Now consider the image $\sigma \mapsto \tilde{\rho}(\sigma)$ of this curve under $\Pi$. It suffices to show that its tangent $p$ at $\sigma=0$ satisfies (60). Indeed, by definition of $\Pi$,

$$
\begin{equation*}
\int \tilde{\rho}(\sigma) \zeta=\int \rho_{0}(\zeta \circ \tilde{\Phi}(\sigma)) \quad \text { for all functions } \zeta \text { on } \mathbb{R}^{N} \tag{62}
\end{equation*}
$$

which we differentiate w. r. t. $\sigma$ and evaluate at $\sigma=0$,

$$
\begin{aligned}
\int \frac{\partial \tilde{\rho}}{\partial \sigma_{\mid \sigma=0}} \zeta & \stackrel{(61)}{=} \int \rho_{0}(\nabla \zeta \circ \Phi) \cdot(u \circ \Phi) \\
& =\int \rho \nabla \zeta \cdot u \text { for all functions } \zeta \text { on } \mathbb{R}^{N} .
\end{aligned}
$$

On the other hand, we have by definition (8) of $p$, after integration by parts,

$$
\int \rho \nabla \zeta \cdot \nabla p=\int \frac{\partial \tilde{\rho}}{\partial \sigma}{ }_{\mid \sigma=0} \zeta \text { for all functions } \zeta \text { on } \mathbb{R}^{N} .
$$

This establishes (60).
In view of the definition (9) and of (56), the identity (54) turns into

$$
\int \rho|\nabla p|^{2}=\inf _{T_{\Phi} \Pi \cdot u=p} \int \rho|u|^{2},
$$

which now is an immediate consequence of the characterization (60) of $T_{\Phi} \Pi . u$.

### 4.2 A property of the map $\Pi$

The map $\Pi$ has the following important property. Let $\sigma \mapsto \Phi(\sigma)$ be a geodesic on $\left(\mathcal{M}^{*}, g^{*}\right)$. Then

$$
\begin{equation*}
\frac{d \Phi}{d \sigma}(0) \in\left(\operatorname{ker} T_{\Phi(0)} \Pi\right)^{\perp} \quad \text { implies } \quad \frac{d \Phi}{d \sigma}(\sigma) \in\left(\operatorname{ker} T_{\Phi(\sigma)} \Pi\right)^{\perp} \quad \text { for all } \sigma . \tag{63}
\end{equation*}
$$

Let us establish this property. Since $\left(\mathcal{M}^{*}, g^{*}\right)$ carries the geometry of the ambient euclidean $L^{2}$-space with weight $\rho_{0}$, the geodesic equation is

$$
\frac{\partial^{2} \Phi}{\partial \sigma^{2}}=0
$$

We express the geodesic equation in terms of the tangent field $\sigma \mapsto u(\sigma)$ given by by

$$
\begin{equation*}
\frac{\partial \Phi}{\partial \sigma}=u \circ \Phi \tag{64}
\end{equation*}
$$

Since

$$
\begin{aligned}
\frac{\partial^{2} \Phi}{\partial \sigma^{2}} & \stackrel{(64)}{=} \frac{\partial}{\partial \sigma}(u \circ \Phi) \\
& =\frac{\partial u}{\partial \sigma} \circ \Phi+(\mathrm{D} u \circ \Phi) \cdot \frac{\partial \Phi}{\partial \sigma} \\
& \stackrel{(64)}{=}\left(\frac{\partial u}{\partial \sigma}+\mathrm{D} u . u\right) \circ \Phi,
\end{aligned}
$$

where $\mathrm{D} u$ denotes the Jacobian of $u$ w. r. t. the spatial variables, the geodesic equation reads

$$
\begin{equation*}
\frac{\partial u}{\partial \sigma}+\mathrm{D} u . u=0 \tag{65}
\end{equation*}
$$

According to (59), the left hand side of (63) means that there exists a function $p_{0}$ on $\mathbb{R}^{N}$ such that $u(0)=\nabla p_{0}$. Now let the function $\tilde{p}(\sigma, x)$ solve the Hamilton-Jacobi equation

$$
\frac{\partial \tilde{p}}{\partial \sigma}+\frac{1}{2}|\nabla \tilde{p}|^{2}=0 \quad \text { with initial data } p_{0}
$$

Then its spatial gradient $\tilde{u}=\nabla \tilde{p}$ solves

$$
\frac{\partial \tilde{u}}{\partial \sigma}+\mathrm{D} \tilde{u} . \tilde{u}=0 \quad \text { with initial data } \nabla p_{0} .
$$

Hence $\tilde{u}$ and $u$ solve the same evolution equation with identical initial data. Therefore, $\tilde{u}$ and $u$ coincide. In particular,

$$
u(\sigma)=\nabla \tilde{p}(\sigma) \quad \text { for all } \sigma
$$

which according to (59) entails the right hand side of (63).

### 4.3 Identification of geodesics and induced distance

We will first characterize geodesics and the induced distance on $(\mathcal{M}, g)$ in terms of geodesics and the induced distance on $\left(\mathcal{M}^{*}, g^{*}\right)$. For this, we forget about where our structure $\Pi:\left(\mathcal{M}^{*}, g^{*}\right) \rightarrow(\mathcal{M}, g)$ came from and work exclusively within the abstract framework of a Riemannian submersion with the additional property established in the previous subsection.

The first observation states how the 'energy' of curves transforms under $\Pi$ : Let $\sigma \mapsto \Phi(\sigma)$ be a curve on $\mathcal{M}^{*}$. Consider its image $\sigma \mapsto \rho(\sigma)$ on $\mathcal{M}$ under $\Pi$, that is: $\rho(\sigma)=\Pi(\Phi(\sigma))$. Then

$$
\begin{align*}
& \int g_{\rho}\left(\frac{d \rho}{d \sigma}, \frac{d \rho}{d \sigma}\right) d \sigma \leq \int g_{\Phi}^{*}\left(\frac{d \Phi}{d \sigma}, \frac{d \Phi}{d \sigma}\right) d \sigma  \tag{66}\\
& \text { with equality if } \quad \frac{d \Phi}{d \sigma} \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp} .
\end{align*}
$$

Indeed, we have $\frac{d \rho}{d \sigma}=T_{\Phi} \Pi \cdot \frac{d \Phi}{d \sigma}$, and therefore, according to (54),

$$
g_{\rho}\left(\frac{d \rho}{d \sigma}, \frac{d \rho}{d \sigma}\right) \leq g_{\Phi}^{*}\left(\frac{d \Phi}{d \sigma}, \frac{d \Phi}{d \sigma}\right)
$$

with equality if $\frac{d \Phi}{d \sigma} \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$.
The second observation states what happens to geodesics under $\Pi$.
If $\sigma \mapsto \Phi(\sigma)$ is a geodesic on $\left(\mathcal{M}^{*}, g^{*}\right)$ with $\frac{d \Phi}{d \sigma} \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$,
then its image $\sigma \mapsto \rho(\sigma)$ is a geodesic on $(\mathcal{M}, g)$.
If $\sigma \mapsto \rho(\sigma)$ is a geodesic on $(\mathcal{M}, g)$ with $\rho(0)=\rho_{0}$, then there exists a geodesic $\sigma \mapsto \Phi(\sigma)$ on $\left(\mathcal{M}^{*}, g^{*}\right)$ with $\left.\Phi(0)=\mathrm{id}, \frac{d \Phi}{d \sigma} \in\right\}$ $\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ and such that $\sigma \mapsto \rho(\sigma)$ is its image under $\Pi$. $\}$

Indeed, for (67), it suffices to show that $\sigma \mapsto \rho(\sigma)$ has lowest energy among all small variations on small $\sigma$-intervals, using the fact that $\sigma \mapsto \Phi(\sigma)$ has the same property. Let $(\epsilon, \sigma) \mapsto \tilde{\rho}(\epsilon, \sigma)$ be a given variation of $\sigma \mapsto \rho(\sigma)$, that is: $\tilde{\rho}(0, \sigma)=\rho(\sigma)$. Since $T_{\phi} \Pi$ is an isomorphism of $\left(\operatorname{ker} T_{\phi} \Pi\right)^{\perp}$ onto $T_{\Pi(\Phi)} \mathcal{M}$, and since $\frac{d \Phi}{d \sigma} \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$, we can 'lift' the variation $(\epsilon, \sigma) \mapsto \tilde{\rho}(\epsilon, \sigma)$ to a variation $(\epsilon, \sigma) \mapsto \tilde{\Phi}(\epsilon, \sigma)$ of $\sigma \mapsto \Phi(\sigma)$, that is: $\Pi(\tilde{\Phi}(\epsilon, \sigma))=\tilde{\rho}(\epsilon, \sigma)$, with $\frac{d \tilde{\Phi}}{d \sigma} \in\left(\operatorname{ker} T_{\tilde{\Phi}} \Pi\right)^{\perp}$. Therefore the energy of $\sigma \mapsto \rho(\sigma)$ does not exceed the energy of the variation $\sigma \mapsto \tilde{\rho}(\epsilon, \sigma)$ for any $\epsilon$ :

$$
\begin{aligned}
\int g_{\rho}\left(\frac{d \rho}{d \sigma}, \frac{d \rho}{d \sigma}\right) d \sigma & \stackrel{(66)}{=} \int g_{\Phi}^{*}\left(\frac{d \Phi}{d \sigma}, \frac{d \Phi}{d \sigma}\right) d \sigma \\
& \leq \int g_{\tilde{\Phi}}^{*}\left(\frac{d \tilde{\Phi}}{d \sigma}, \frac{d \tilde{\Phi}}{d \sigma}\right) d \sigma \\
& \stackrel{(66)}{=} \int g_{\tilde{\rho}}\left(\frac{d \tilde{\rho}}{d \sigma}, \frac{d \tilde{\rho}}{d \sigma}\right) d \sigma .
\end{aligned}
$$

The argument for (68) goes as follows: Let $\sigma \mapsto \rho(\sigma)$ be a geodesic on $(\mathcal{M}, g)$ with $\rho(0)=\rho_{0}$. Let $\sigma \mapsto \Phi(\sigma)$ be the geodesic on $\left(\mathcal{M}^{*}, g^{*}\right)$ with $\Phi(0)=$ id and

$$
T_{\Phi(0)} \Pi \cdot \frac{d \Phi}{d \sigma}(0)=\frac{d \rho}{d \sigma}(0) \quad \text { and } \quad \frac{d \Phi}{d \sigma}(0) \in\left(\operatorname{ker} T_{\Phi(0)} \Pi\right)^{\perp}
$$

According to the previous subsection, namely (63), the last property is preserved along the geodesic:

$$
\frac{d \Phi}{d \sigma}(\sigma) \in\left(\operatorname{ker} T_{\Phi(\sigma)} \Pi\right)^{\perp} \quad \text { for all } \sigma
$$

By (67), this implies that the image under $\Pi, \sigma \mapsto \Pi(\Phi(\sigma))$, is a geodesic on $(\mathcal{M}, g)$. By construction, it has the same initial data as $\sigma \mapsto \rho(\sigma)$. Hence both geodesics coincide:

$$
\Pi(\Phi(\sigma))=\rho(\sigma) \quad \text { for all } \sigma
$$

The third observation states what happens to the induced distance under $\Pi$. Let $d^{*}$ denote the induced distance on $\left(\mathcal{M}^{*}, g^{*}\right)$ and $d$ the one on $(\mathcal{M}, g)$. Let $\rho \in \mathcal{M}$ be arbitrary; then

- For all $\Phi$ with $\Pi(\Phi)=\rho$,

$$
\begin{equation*}
d\left(\rho_{0}, \rho\right)^{2} \leq d^{*}(\operatorname{id}, \Phi)^{2} \tag{69}
\end{equation*}
$$

- There exists a $\Phi$ with $\Pi(\Phi)=\rho$ and

$$
\begin{equation*}
d\left(\rho_{0}, \rho\right)^{2} \geq d^{*}(\mathrm{id}, \Phi)^{2} \tag{70}
\end{equation*}
$$

We observe that (69) and (70) imply

$$
\begin{equation*}
d\left(\rho_{0}, \rho\right)^{2}=\inf _{\Pi(\Phi)=\rho} d^{*}(\mathrm{id}, \Phi)^{2} . \tag{71}
\end{equation*}
$$

Let us start with (69). Indeed, let $[0,1] \ni \sigma \mapsto \tilde{\Phi}(\sigma)$ be any curve on $\mathcal{M}^{*}$ with $\tilde{\Phi}(0)=$ id and $\tilde{\Phi}(1)=\Phi$. Consider its image $[0,1] \ni \sigma \mapsto \tilde{\rho}(\sigma)$ under $\Pi$. By assumption, $\tilde{\rho}(1)=\rho$, and by definition of $\Pi, \tilde{\rho}(0)=\rho_{0}$. Therefore

$$
\begin{aligned}
& d\left(\rho_{0}, \rho\right)^{2} \leq \int_{0}^{1} g_{\tilde{\rho}}\left(\frac{d \tilde{\rho}}{d \sigma}, \frac{d \tilde{\rho}}{d \sigma}\right) d \sigma \\
&(66) \\
& \leq \int_{0}^{1} g_{\tilde{\Phi}}^{*}\left(\frac{d \tilde{\Phi}}{d \sigma}, \frac{d \tilde{\Phi}}{d \sigma}\right) d \sigma .
\end{aligned}
$$

Since $\tilde{\Phi}$ was an arbitrary curve connecting id to $\Phi$, this inequality yields (69). Now let $[0,1] \ni \sigma \mapsto \tilde{\rho}(\sigma)$ be a curve connecting $\rho_{0}$ to $\rho$ with minimal energy. According to (68), there exists a curve $[0,1] \ni \sigma \mapsto \Phi(\sigma)$ on $\left(\mathcal{M}^{*}, g^{*}\right)$ such that

$$
\frac{d \tilde{\Phi}}{d \sigma} \in\left(\operatorname{ker}_{\tilde{\Phi}} \Pi\right)^{\perp}, \quad \tilde{\Phi}(0)=\text { id } \quad \text { and } \quad \Pi(\tilde{\Phi}(\sigma))=\tilde{\rho}(\sigma)
$$

In particular, $\Phi:=\tilde{\Phi}(1)$ satisfies $\Pi(\Phi)=\rho$, and we have

$$
\begin{aligned}
d\left(\rho_{0}, \rho\right)^{2} & =\int_{0}^{1} g_{\tilde{\rho}}\left(\frac{d \tilde{\rho}}{d \sigma}, \frac{d \tilde{\rho}}{d \sigma}\right) d \sigma \\
& \stackrel{(66)}{=} \int_{0}^{1} g_{\tilde{\Phi}}^{*}\left(\frac{d \tilde{\Phi}}{d \sigma}, \frac{d \tilde{\Phi}}{d \sigma}\right) d \sigma \\
& \geq d^{*}(\mathrm{id}, \Phi)^{2} .
\end{aligned}
$$

This establishes (70).
We will now use the above characterization of geodesics on $(\mathcal{M}, g)$ in terms of geodesics on $\left(\mathcal{M}^{*}, g^{*}\right)$ and our good understanding of the latter to identify the former. Since $\left(\mathcal{M}^{*}, g^{*}\right)$ carries the geometry of the ambient $L^{2}$-space with weight $\rho_{0}$, geodesics $\sigma \mapsto \Phi(\sigma)$ are characterized by

$$
\begin{equation*}
\frac{\partial^{2} \Phi}{\partial \sigma^{2}}=0 \tag{72}
\end{equation*}
$$

Now let $\sigma \mapsto \rho(\sigma)$ be a geodesic on $(\mathcal{M}, g)$ with the initial data

$$
\begin{equation*}
\rho(0)=\rho_{0} \quad \text { and } \quad \frac{d \rho}{d \sigma}(0)=s \tag{73}
\end{equation*}
$$

We represent the tangent vector $s \in T_{\rho_{0}} \mathcal{M}$ by

$$
\begin{equation*}
-\nabla \cdot\left(\rho_{0} \nabla p\right)=s \tag{74}
\end{equation*}
$$

According to (68), there exists a geodesic $\sigma \mapsto \Phi(\sigma)$ on $\left(\mathcal{M}^{*}, g^{*}\right)$ with $\Phi(0)=$ id, $\frac{d \Phi}{d \sigma} \in\left(\operatorname{ker} T_{\Phi} \Pi\right)^{\perp}$ and such that $\sigma \mapsto \rho(\sigma)$ is its image under $\Pi$, that is

$$
\rho(\sigma)=\Phi(\sigma) \# \rho_{0} \quad \text { for all } \sigma
$$

Since in particular, $\Phi(0)=$ id and

$$
T_{\mathrm{id}} \Pi \cdot \frac{d \Phi}{d \sigma}(0)=s \quad \text { and } \quad \frac{d \Phi}{d \sigma}(0) \in\left(\operatorname{ker} T_{\mathrm{id}} \Pi\right)^{\perp}
$$

we must have by our characterization of $T_{\mathrm{id}} \Pi$

$$
\frac{\partial \Phi}{\partial \sigma}(0)=\nabla p
$$

Together with (72), we infer that $\Phi(\sigma)$ is of the form

$$
\Phi(\sigma)=\nabla\left(\frac{1}{2}|y|^{2}+\sigma p\right)
$$

Therefore, we have characterized our geodesic $\sigma \mapsto \rho(\sigma)$ with initial data (73) as

$$
\begin{equation*}
\rho(\sigma)=\left[\nabla\left(\frac{1}{2}|y|^{2}+\sigma p\right)\right] \# \rho_{0} \tag{75}
\end{equation*}
$$

where $p$ is related to $s$ by (74).
We will now use the above characterization of the induced distance on $(\mathcal{M}, g)$ in terms of the induced distance on $\left(\mathcal{M}^{*}, g^{*}\right)$ and our good understanding of the latter to identify the former. Since $\left(\mathcal{M}^{*}, g^{*}\right)$ carries the geometry of the ambient $L^{2}$-space with weight $\rho_{0}, d^{*}$ is given by

$$
d^{*}\left(\Phi_{0}, \Phi_{1}\right)^{2}=\int \rho_{0}\left|\Phi_{0}-\Phi_{1}\right|^{2}
$$

We therefore obtain from (71) that

$$
d\left(\rho_{0}, \rho\right)^{2}=\inf _{\rho=\Phi \# \rho_{0}} \int \rho_{0}|\mathrm{id}-\Phi|^{2}
$$

Hence we have identified the induced distance on $\mathcal{M}$ with what is called the Wasserstein distance, which we formally introduce in section 5.

### 4.4 Computation of the Hessians Hess $E$ and Hess $M$

The Hessian Hess $F$ of a function $F$ on a Riemannian manifold $(\mathcal{M}, g)$ can be computed by taking second derivatives of $F$ along geodesics. More precisely, if $\sigma \mapsto \rho(\sigma)$ is a geodesic on $(\mathcal{M}, g)$ with

$$
\rho(0)=\rho_{0} \quad \text { and } \quad \frac{d \rho}{d \sigma}(0)=s
$$

then

$$
\begin{equation*}
g_{\rho_{0}}\left(s, \operatorname{Hess} F_{\mid \rho_{0}} s\right)=\frac{d^{2}}{d \sigma^{2}} F(\rho(\sigma))_{\mid \sigma=0} . \tag{76}
\end{equation*}
$$

As always, we represent the tangent vector $s \in T_{\rho_{0}} \mathcal{M}$ by

$$
-\nabla \cdot\left(\rho_{0} \nabla p\right)=s
$$

In the previous subsection, we characterized the geodesic $\sigma \mapsto \rho(\sigma)$ as

$$
\begin{equation*}
\rho(\sigma)=\nabla \varphi(\sigma) \# \rho_{0} \tag{77}
\end{equation*}
$$

where the function $\varphi(\sigma)$ on $\mathbb{R}^{N}$ is given by

$$
\begin{equation*}
\varphi(\sigma, y)=\frac{1}{2}|y|^{2}+\sigma p(y) . \tag{78}
\end{equation*}
$$

Hence convexity of a function $F$ on the Riemannian manifold $(\mathcal{M}, g)$ reduces to McCann's 'displacement convexity' [6]. McCann introduced, established and used this notion for our energy functional $E$ to prove uniqueness for a variational problem on $\mathcal{M}$ - without referral to the Riemannian structure. As a guideline for our rigorous arguments in the next section, it will be convenient to explicitly find Hess $E_{\left.\right|_{\rho_{0}}}$ (as opposed to just showing that it is positive semi definite). Therefore the calculation which now follows deviate a bit from McCann's.

We observe that (77) can be reformulated as

$$
\operatorname{det} \mathrm{D}^{2} \varphi(\sigma)(\rho(\sigma) \circ \nabla \varphi(\sigma))=\rho_{0}
$$

so that

$$
\begin{equation*}
E(\rho(\sigma))=\int e\left(\frac{\rho_{0}}{\operatorname{det} \mathrm{D}^{2} \varphi(\sigma)}\right) \operatorname{det} \mathrm{D}^{2} \varphi(\sigma) \tag{79}
\end{equation*}
$$

where $\mathrm{D}^{2} \varphi(\sigma)$ denotes the $N \times N$-matrix of second spatial derivatives of $\varphi(\sigma)$ and $e$ the energy density, as defined in (21).

Guided by the above, we consider a curve $\sigma \mapsto A(\sigma)$ in the space of symmetric and positive definite $N \times N$-matrices and a positive number $z>0$. Let us recall that the energy density $e$ and the osmotic pressure $\pi$ (defined in (20)) are related by

$$
\pi(z)=z e^{\prime}(z)-e(z)
$$

Therefore, we have

$$
\begin{aligned}
\frac{d}{d \sigma}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right]= & -\pi\left(\frac{z}{\operatorname{det} A}\right) \frac{d}{d \sigma} \operatorname{det} A \\
\frac{d^{2}}{d \sigma^{2}}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right]= & \pi^{\prime}\left(\frac{z}{\operatorname{det} A}\right) \frac{z}{(\operatorname{det} A)^{2}}\left(\frac{d}{d \sigma} \operatorname{det} A\right)^{2} \\
& -\pi\left(\frac{z}{\operatorname{det} A}\right) \frac{d^{2}}{d \sigma^{2}} \operatorname{det} A
\end{aligned}
$$

By elementary linear algebra,

$$
\begin{aligned}
\frac{d}{d \sigma} \operatorname{det} A= & \operatorname{tr}\left(A^{-1} \frac{\partial A}{\partial \sigma}\right) \operatorname{det} A \\
\frac{d^{2}}{d \sigma^{2}} \operatorname{det} A= & -\operatorname{tr}\left(A^{-1} \frac{\partial A}{\partial \sigma}\right)^{2} \operatorname{det} A+\left(\operatorname{tr}\left(A^{-1} \frac{\partial A}{\partial \sigma}\right)\right)^{2} \operatorname{det} A \\
& +\operatorname{tr}\left(A^{-1} \frac{d^{2} A}{d \sigma^{2}}\right) \operatorname{det} A
\end{aligned}
$$

Hence if the curve $\sigma \mapsto A(\sigma)$ additionally satisfies $\frac{d^{2} A}{d \sigma^{2}}=0$, we obtain

$$
\begin{aligned}
\frac{d^{2}}{d \sigma^{2}}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right]= & \left(w \pi^{\prime}(w)-\pi(w)\right)\left(\operatorname{tr}\left(A^{-1} B\right)\right)^{2} \operatorname{det} A \\
& +\pi(w) \operatorname{tr}\left(A^{-1} B\right)^{2} \operatorname{det} A,
\end{aligned}
$$

where we have used the abbreviations

$$
B:=\frac{d A}{d \sigma} \quad \text { and } \quad w:=\frac{z}{\operatorname{det} A} .
$$

Since

$$
\left(A^{-1} B\right)^{2}=A^{-1 / 2} C^{2} A^{1 / 2} \quad \text { with } \quad C:=A^{-1 / 2} B A^{-1 / 2},
$$

where $C$ is a symmetric matrix, we have

$$
\begin{equation*}
\operatorname{tr}\left(A^{-1} B\right)^{2}=\operatorname{tr} C^{2} \geq \frac{1}{N}(\operatorname{tr} C)^{2}=\frac{1}{N}\left(\operatorname{tr}\left(A^{-1} B\right)\right)^{2} . \tag{80}
\end{equation*}
$$

Since $\pi(w)=w^{m} \geq 0$, we therefore obtain

$$
\frac{d^{2}}{d \sigma^{2}}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right] \geq\left(w \pi^{\prime}(w)-\left(1-\frac{1}{N}\right) \pi(w)\right)\left(\operatorname{tr}\left(A^{-1} B\right)\right)^{2} \operatorname{det} A
$$

Since $w \pi^{\prime}(w)-\left(1-\frac{1}{N}\right) \pi(w)=\left(m-\left(1-\frac{1}{N}\right)\right) w^{m} \geq 0$ by our assumption $m \geq 1-\frac{1}{N}$, this implies

$$
\begin{equation*}
\frac{d^{2}}{d \sigma^{2}}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right] \geq 0 \tag{81}
\end{equation*}
$$

For later reference, we notice that if in addition $A(0)=\mathrm{id}$,

$$
\begin{equation*}
{\frac{d^{2}}{d \sigma^{2}}}_{\mid \sigma=0}\left[e\left(\frac{z}{\operatorname{det} A}\right) \operatorname{det} A\right]=\left(z \pi^{\prime}(z)-\pi(z)\right)(\operatorname{tr} B)^{2}+\pi(z) \operatorname{tr} B^{2} . \tag{82}
\end{equation*}
$$

Now consider $\mathrm{D}^{2} \varphi(\sigma)$. We observe that 1) $\mathrm{D}^{2} \varphi(\sigma)$ is symmetric, 2) $\mathrm{D}^{2} \varphi(\sigma)$ is positive definite (for sufficiently small $\sigma$ ) since $\left.\mathrm{D}^{2} \varphi(0)=\mathrm{id}, 3\right) \frac{\partial^{2}}{\partial \sigma^{2}} \mathrm{D}^{2} \varphi(\sigma)=0$ because of (78). Hence we may apply the above to $A(\sigma)=\mathrm{D}^{2} \varphi(\sigma)$ and obtain

$$
\frac{d^{2}}{d \sigma^{2}} E(\rho(\sigma)) \stackrel{(79)}{=} \int \frac{\partial^{2}}{\partial \sigma^{2}}\left[e\left(\frac{\rho_{0}}{\operatorname{det} \mathrm{D} \Phi}\right) \operatorname{det} \mathrm{D} \Phi\right]
$$

$$
\stackrel{(81)}{\geq} 0 .
$$

Since $\left.\frac{\partial}{\partial \sigma}\right|_{\sigma=0} \mathrm{D}^{2} \varphi \stackrel{(78)}{=} \mathrm{D}^{2} p$ and $\mathrm{D}^{2} \varphi(0)=0$, we also get

$$
\begin{aligned}
\frac{d^{2}}{d \sigma^{2}}{ }_{\mid \sigma=0} E(\rho(\sigma)) & =\int \frac{\partial^{2}}{\partial \sigma^{2}}{ }_{\mid \sigma=0}\left[e\left(\frac{\rho_{0}}{\operatorname{det} \mathrm{D}^{2} \varphi}\right) \operatorname{det} \mathrm{D}^{2} \varphi\right] \\
& \stackrel{(82)}{=} \int\left\{\left(\pi^{\prime}\left(\rho_{0}\right) \rho_{0}-\pi\left(\rho_{0}\right)\right)\left(\nabla^{2} p\right)^{2}+\pi\left(\rho_{0}\right) \operatorname{tr}\left(\mathrm{D}^{2} p\right)^{2}\right\}
\end{aligned}
$$

We conclude by

$$
\begin{align*}
g_{\rho_{0}}\left(s, \operatorname{Hess} E_{\mid \rho_{0}} s\right) & \stackrel{(76)}{=} \frac{d^{2}}{d \sigma^{2}}{ }_{\mid \sigma=0} E(\rho(\sigma)) \\
& =\int\left\{\left(\pi^{\prime}\left(\rho_{0}\right) \rho_{0}-\pi\left(\rho_{0}\right)\right)\left(\nabla^{2} p\right)^{2}+\pi\left(\rho_{0}\right) \operatorname{tr}\left(D^{2} p\right)^{2}\right\} \\
& \geq 0 . \tag{83}
\end{align*}
$$

This establishes the first part of (27). Let us point out again that it is the condition $m \geq 1-\frac{1}{N}$ which ensures that $E$ is convex on $(\mathcal{M}, g)$.

Let us now identify Hess $M_{\mid \rho_{0}}$. It follows immediately from (77) that

$$
M(\rho(\sigma))=\int \rho_{0} \frac{1}{2}|\nabla \varphi(\sigma)|^{2} .
$$

Hence we obtain

$$
\begin{align*}
g_{\rho_{0}}\left(s, \operatorname{Hess} M_{\mid \rho_{0}} s\right) & \stackrel{(76)}{=} \frac{d^{2}}{d \sigma^{2}}{ }_{\mid \sigma=0} M(\rho(\sigma)) \\
& \stackrel{(77)}{=} \int \rho_{0}\left|\frac{\partial \nabla \varphi}{\partial \sigma}{ }_{\mid \sigma=0}\right|^{2} \\
& \stackrel{(78)}{=} \int \rho_{0}|\nabla p|^{2} \\
& \stackrel{(9)}{=} g_{\rho_{0}}(s, s) . \tag{84}
\end{align*}
$$

This establishes the second part of (27).

## 5 Rigorous results

### 5.1 Weak solutions of the porous medium equation

In case of $m>1$ and for non-zero initial data with compact support, there is no (classically) differentiable solution of the porous medium equation. We therefore must work with the notion of a weak solution. The well-established existence and uniqueness theory for weak solutions is based on the traditional gradient flow approach, as presented in the subsection 1.3. In particular, existence is based on the identity (5) in subsection 1.2 , which in the traditional approach reads as

$$
\frac{d}{d t} \int \frac{1}{m+1} \rho(t)^{m+1}=-\int\left|\nabla \rho^{m}(t)\right|^{2}
$$

This identity yields the essential a priori estimates. Uniqueness is based on the convexity of the functional in the traditional approach, which leads to a contraction property of the semi group in the induced norm (remember that in the traditional approach, the space carries the geometry of a convex subset
of a euclidean function space, so that intrinsic convexity of the functional reduces to ordinary convexity). Here that means that if $\rho_{0}, \rho_{1}$ are solutions, then

$$
\frac{d}{d t} \int|\nabla p(t)|=\int\left(\rho_{1}(t)-\rho_{0}(t)\right)\left(\rho_{1}(t)^{m}-\rho_{0}(t)^{m}\right) \leq 0
$$

where, in the spirit of (7),

$$
-\nabla^{2} p(t)=\rho_{1}(t)-\rho_{0}(t)
$$

Definition 1 Let $\rho_{0}$ be a measurable and non negative function on $\mathbb{R}^{N}$ with

$$
\int \frac{1}{m+1} \rho_{0}^{m+1}<\infty
$$

Let $\rho$ be a measurable and non negative function on $[0, \infty) \times \mathbb{R}^{N}$ with

$$
\text { ess } \sup _{t \in[0, \infty)} \int \frac{1}{m+1} \rho(t)^{m+1}<\infty .
$$

Then $\rho^{m}$ is locally integrable, more precisely

$$
\operatorname{ess} \sup _{t \in[0, \infty)} \int\left(\rho^{m}(t)\right)^{(m+1)^{*}}<\infty
$$

where $(m+1)^{*}$ denotes the dual exponent to $m+1$. Assume further that $\rho^{m}$ has a distributional spatial gradient $\nabla \rho^{m}$ satisfying

$$
\int_{0}^{\infty} \int\left|\nabla \rho^{m}(t)\right|^{2} d t<\infty
$$

Then $\rho$ is called a weak solution of the porous medium equation with initial data $\rho_{0}$ if

$$
\begin{aligned}
& \int_{(0, \infty) \times \boldsymbol{R}^{N}}\left\{-\rho \frac{\partial \zeta}{\partial t}+\nabla \rho^{m} \cdot \nabla \zeta\right\}=\int \rho_{0} \zeta(0) \\
& \text { for all } \zeta \in C_{0}^{\infty}\left((-\infty, \infty) \times \mathbb{R}^{N}\right)
\end{aligned}
$$

### 5.2 The Wasserstein metric

In subsection 4.3, we formally derived that the induced metric $d$ on $(\mathcal{M}, g)$ is given by

$$
d\left(\rho_{0}, \rho_{1}\right)^{2}=\inf _{\rho_{1}=\Phi \# \rho_{0}} \int \rho_{0}|\operatorname{id}-\Phi|^{2} .
$$

Morally speaking, this is the Wasserstein metric. The precise definition of the Wasserstein metric relaxes the above variational problem. This is done by embedding the set of one-to-one transformations $\Phi$ with $\rho_{1}=\Phi \# \rho_{0}$ into the set of all probability measures $\mu$ on $\mathbb{R}^{N} \times \mathbb{R}^{N}$ with marginals given by the Lebesgue densities $\rho_{0}, \rho_{1}$ via

$$
\begin{equation*}
\mu=(\mathrm{id} \times \Phi) \# \rho_{0} \tag{85}
\end{equation*}
$$

that is

$$
\begin{aligned}
\int \zeta\left(x_{0}, x_{1}\right) \mu\left(d x_{0} d x_{1}\right)= & \int \rho_{0}\left(x_{0}\right) \zeta\left(x_{0}, \Phi\left(x_{0}\right)\right) d x_{0} \\
& \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N} \times \mathbb{R}^{N}\right) .
\end{aligned}
$$

Then

$$
\int \rho_{0}|\operatorname{id}-\Phi|^{2}=\int\left|y_{0}-y_{1}\right|^{2} \mu\left(d y_{0}, d y_{1}\right)
$$

and it is the latter functional one minimizes on the set of all probability measures $\mu$ with marginals $\rho_{0} d y_{0}$ and $\rho_{1} d y_{1}$. The relaxed variational problem is one version of the Monge-Kantorowicz mass transference problems; the $\mu$ 's are called "transference plans", the function $\left|y_{0}-y_{1}\right|^{2}$ is the "cost" of transferring a unit mass from $y_{0}$ to $y_{1}$.

Definition 2 For two non negative Borel measures $\mu_{0}$ and $\mu_{1}$ of equal mass, we introduce

$$
\begin{aligned}
& P\left(\mu_{0}, \mu_{1}\right) \\
&=\left.\left.\left\{\begin{array}{l}
\text { non negative Borel measure } \mu \text { on } \mathbb{R}^{N} \times \mathbb{R}^{N} \mid \\
\\
\\
\\
\\
\\
\\
\int \zeta\left(y_{0}\right) \mu\left(d y_{0} d y_{1}\right)=\int \zeta\left(y_{0}\right) \mu_{0}\left(d y_{0}\right) \text { and }
\end{array}\right] . d y_{0} d y_{1}\right)=\int \zeta\left(y_{1}\right) \mu_{1}\left(d y_{1}\right) \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right)\right\} .
\end{aligned}
$$

$d\left(\mu_{0}, \mu_{1}\right)^{2}$ is defined as

$$
\begin{equation*}
d\left(\mu_{0}, \mu_{1}\right)^{2}=\inf _{\mu \in P\left(\mu_{0}, \mu_{1}\right)} \int\left|y_{1}-y_{0}\right|^{2} \mu\left(d y_{0} d y_{1}\right) . \tag{86}
\end{equation*}
$$

If $\mu_{0}$ and $\mu_{1}$ have Lebesgue densities $\mu_{0}=\rho_{0} d y_{0}$ resp. $\mu_{1}=\rho_{1} d y_{1}$, we also write

$$
d\left(\rho_{0}, \rho_{1}\right)^{2}=d\left(\mu_{0}, \mu_{1}\right)^{2}
$$

The space $P\left(\mu_{0}, \mu_{1}\right)$ always contains the product measure $\mu_{0} \times \mu_{1}$. Hence $d\left(\mu_{0}, \mu_{1}\right) \in[0, \infty]$ is well defined. If the second moments of $\mu_{0}$ and $\mu_{1}$ are finite, then the transference plan $\mu_{0} \times \mu_{1}$ has finite cost, so that $d\left(\mu_{0}, \mu_{1}\right) \in$ $[0, \infty)$. It is then an easy exercise in soft methods that the variational problem (86) admits a minimizer of finite cost. It has been known to the probabilists for a long time that $d$ indeed defines a metric on the space of probability measures on $\mathbb{R}^{N}$ with finite second moments. This distance function is popular in probability theory since it metrizes the topology of weak-* convergence (up to second moments). We found the few results on $d$ we need in [24] or [16]. We summarize them in the following Lemma.

Lemma 1 Let $\left\{\mu_{0, \nu}\right\}_{\nu \uparrow \infty}$ and $\left\{\mu_{1, \nu}\right\}_{\nu \uparrow \infty}$ be two sequences of non negative Borel measures on $\mathbb{R}^{N}$. We assume that the masses of $\mu_{0, \nu}$ and $\mu_{1, \nu}$ are finite and equal and that there exist two non negative Borel measures $\mu_{0}$ and $\mu_{1}$ on $\mathbb{R}^{N}$ of finite mass such that

$$
\int \zeta d \mu_{i}=\lim _{\nu \uparrow \infty} \int \zeta d \mu_{i, \nu} \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right) \quad \text { and } i=0,1 .
$$

Then

$$
d\left(\mu_{0}, \mu_{1}\right)^{2} \leq \liminf _{\nu \uparrow \infty} d\left(\mu_{0, \nu}, \mu_{1, \nu}\right)^{2} .
$$

If in addition

$$
\int \frac{1}{2}|y|^{2} d \mu_{i}=\lim _{\nu \uparrow \infty} \int \frac{1}{2}|y|^{2} d \mu_{i, \nu} \quad \text { for } i=0,1 .
$$

then

$$
d\left(\mu_{0}, \mu_{1}\right)^{2}=\lim _{\nu \uparrow \infty} d\left(\mu_{0, \nu}, \mu_{1, \nu}\right)^{2} .
$$

The variational problem in (86) has recently received some attention by analysts. If the measures $\mu_{0}$ and $\mu_{1}$ have bounded support and Lebesgue densities $\mu_{0}=\rho_{0} d y_{0}$ resp. $\mu_{1}=\rho_{1} d y_{1}$, Brenier [3] has shown uniqueness of the minimizing transference plan $\mu$ and proved that the support of $\mu$ is the graph of the gradient of a (generically non smooth) convex function, more precisely,

$$
\begin{equation*}
\mu=(\operatorname{id} \times \nabla \varphi) \# \rho_{0} \tag{87}
\end{equation*}
$$

A glance back to (85) then shows that the initial relaxation from one-toone transformations $\Phi$ to transference plans $\mu$ is non essential and just of technical convenience. In particular, (87) yields that

$$
\begin{equation*}
\rho_{1}=\nabla \varphi \# \rho_{0} \tag{88}
\end{equation*}
$$

We also invite the reader to compare (88) with (77) in subsection 4.4.
Caffarelli [4] and Gangbo \& McCann [13, 14, 15] have extended Brenier's result to more general strictly convex cost functions. The case of cost functions of degenerate convexity [11] and concave cost functions [15] is qualitatively different.

### 5.3 The statement of the rigorous result

Theorem 1 Let $m$ satisfy $m>\frac{N}{N+2}$ and $m \geq 1-\frac{1}{N}$. Let $\rho$ be a weak solution of the porous medium equation with initial data $\rho_{0}$ in the sense of Definition 1. We assume that additionally

$$
\int \rho_{0}=1 \quad \text { and } \quad \int \rho_{0} \frac{1}{2}|x|^{2}<\infty
$$

We consider the function $\hat{\rho}$ on $(-\infty, \infty) \times \mathbb{R}^{N}$ given by

$$
\rho(t, x)=\frac{1}{t^{N \alpha}} \hat{\rho}\left(\ln t, \frac{x}{t^{\alpha}}\right),
$$

where $\alpha=\frac{1}{(m-1) N+2}$. Then, in a distributional sense,

$$
\begin{aligned}
\frac{d}{d \tau}\left[\exp (2 \alpha \tau)\left|\operatorname{grad} F_{\mid \hat{\rho}(\tau)}\right|^{2}\right] & \leq 0 \\
\frac{d}{d \tau}\left[\exp (2 \alpha \tau)\left(F(\hat{\rho}(\tau))-F\left(\hat{\rho}_{*}\right)\right)\right] & \leq 0 \\
\frac{d}{d \tau}\left[\exp (2 \alpha \tau) d\left(\hat{\rho}(\tau), \hat{\rho}_{*}\right)^{2}\right] & \leq 0
\end{aligned}
$$

with the understanding that the quantities in the square brackets are finite for $\tau>-\infty$. The precise meaning of $\left|\operatorname{grad} F_{\hat{\rho}}\right|^{2}$ and $F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)$ is given in (90) resp. (91), d denotes the Wasserstein distance as in Definition 2.

Let us now explain what we understand by $\left|\operatorname{grad} F_{\hat{\rho}}\right|^{2}$ and $F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)$ in Theorem 1. In subsection (3.4), we have identified $\left|\operatorname{grad} F_{\hat{\rho}}\right|^{2}$ as

$$
\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}=\int \hat{\rho}|\nabla p|^{2} \quad \text { where } \quad p(y)=e^{\prime}(\hat{\rho}(y))+\alpha \frac{1}{2}|y|^{2}
$$

We observe that thanks to the fundamental relationship $z e^{\prime \prime}(z)=\pi^{\prime}(z)$ between energy density (21) and osmotic pressure (20), we have

$$
\frac{1}{\hat{\rho}} \nabla \pi(\hat{\rho})=\hat{\rho} \nabla e^{\prime}(\hat{\rho})
$$

and thus

$$
\begin{equation*}
\int \frac{1}{\hat{\rho}}|\nabla \pi(\hat{\rho})+\alpha \hat{\rho} y|^{2}=\int \hat{\rho}|\nabla p|^{2}, \tag{89}
\end{equation*}
$$

provided $\hat{\rho}$ is locally bounded away from zero. Observe that even if this is not the case, the l. h. s. of (89) is well defined as a number in $[0, \infty]$, since $\nabla \pi(\hat{\rho})$ vanishes almost everywhere on the set where $\hat{\rho}$ vanishes. It is this weak formulation

$$
\begin{equation*}
\left|\operatorname{grad} F_{\hat{\rho}}\right|^{2}=\int \frac{1}{\hat{\rho}}|\nabla \pi(\hat{\rho})+\alpha \hat{\rho} y|^{2}, \tag{90}
\end{equation*}
$$

we use in Theorem 1.
By $F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)$ we understand

$$
\begin{align*}
& F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)  \tag{91}\\
& \quad=\left\{\begin{array}{cc}
\left(\int e(\hat{\rho})+\alpha \int \hat{\rho} \frac{1}{2}|y|^{2}\right)-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right) & \text { for } m>1, \\
\int\left\{e(\hat{\rho})-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}-\hat{\rho}_{*}\right)\right\} & \text { for } m \leq 1
\end{array}\right\} .
\end{align*}
$$

The second line is inspired by the identity (31) in subsection 3.3. We point out that in both lines, the integrands are non negative; hence the number $F(\hat{\rho})-F\left(\hat{\rho}_{*}\right) \in[0, \infty]$ is well defined.

The main technical difficulty in mimicking the Riemannian calculus is the possible lack of regularity of solutions of the porous medium equation. Our approach is to mimic the Riemannian calculus in a completely smooth setting (Proposition 1) and then to use an approximation argument (in the proof of Theorem 1).

Proposition 1 Let e and $\pi$ be smooth functions on $(0, \infty)$ related by

$$
\begin{equation*}
\pi(z)=z e^{\prime}(z)-e(z) \quad \text { and thus } \quad \pi^{\prime}(z)=z e^{\prime \prime}(z) \tag{92}
\end{equation*}
$$

and satisfying

$$
\begin{gather*}
\pi(z) \geq 0 \quad \text { and } \quad z \pi^{\prime}(z)-\left(1-\frac{1}{N}\right) \pi(z) \geq 0  \tag{93}\\
\lim _{z \downarrow 0} e^{\prime}(z)=-\infty \quad \text { and } \quad \lim _{z \downarrow 0} e(z)=0 . \tag{94}
\end{gather*}
$$

Let the open $\Omega \subset \mathbb{R}^{N}$ satisfy

$$
\Omega \text { is convex and } \partial \Omega \text { is smooth. }
$$

Let the function $\hat{\rho}$ of be a smooth and positive function on $(-\infty, \infty) \times \bar{\Omega}$ which solves

$$
\begin{align*}
\frac{\partial \hat{\rho}}{\partial \tau}-\nabla \cdot(\hat{\rho} \nabla p) & =0 \quad \text { in }(-\infty, \infty) \times \Omega  \tag{95}\\
\hat{\rho} \nabla p \cdot \nu & =0 \quad \text { on }(-\infty, \infty) \times \partial \Omega \tag{96}
\end{align*}
$$

where

$$
p=e^{\prime}(\hat{\rho})+\alpha \frac{1}{2}|y|^{2}
$$

for some fixed $\alpha \geq 0$. We observe that the evolution equation $(95,96)$ conserves mass. Thanks to (94), there exists a smooth stationary solution $\hat{\rho}_{*}$ of $(95,96)$ with the same mass, it is given by

$$
\begin{equation*}
e^{\prime}\left(\hat{\rho}_{*}(y)\right)+\alpha \frac{1}{2}|y|^{2}=\lambda \quad \text { and } \quad \int_{\Omega} \hat{\rho}_{*}=\int_{\Omega} \hat{\rho}(\tau) . \tag{97}
\end{equation*}
$$

Then $\hat{\rho}$ and $\hat{\rho}_{*}$ satisfy

$$
\begin{equation*}
\frac{d}{d \tau}\left[\exp (2 \alpha \tau) \int_{\Omega} \hat{\rho}(\tau)|\nabla p(\tau)|^{2}\right] \leq 0 \tag{98}
\end{equation*}
$$

$$
\begin{gather*}
\frac{d}{d \tau}\left[\exp (2 \alpha \tau)\left(F(\hat{\rho}(\tau))-F\left(\hat{\rho}_{*}\right)\right)\right] \leq 0  \tag{99}\\
\frac{d}{d \tau}\left[\exp (2 \alpha \tau) d\left(\hat{\rho}_{*}, \hat{\rho}(\tau)\right)^{2}\right] \leq 0 \tag{100}
\end{gather*}
$$

where

$$
F(\hat{\rho})=E(\hat{\rho})+\alpha M(\hat{\rho})=\int_{\Omega} e(\hat{\rho})+\alpha \int_{\Omega} \hat{\rho} \frac{1}{2}|y|^{2} .
$$

### 5.4 Proof of the Proposition

We start with the proof of (98). At the center of our attention is

$$
p(y)=e^{\prime}(\hat{\rho}(y))+\alpha \frac{1}{2}|y|^{2},
$$

that is, $p \cong \operatorname{grad} F_{\mid \hat{\rho}}=-\frac{d \hat{\rho}}{d \tau}$. We have

$$
\begin{aligned}
\frac{d}{d \tau} \int_{\Omega} \hat{\rho}|\nabla p|^{2} & =\int_{\Omega}\left\{\hat{\rho} 2 \nabla p \cdot \nabla \partial_{\tau} p+\partial_{\tau} \hat{\rho}|\nabla p|^{2}\right\} \\
& \left.\stackrel{(95)}{=} 2 \int_{\Omega}\left\{\hat{\rho} 2 \nabla p \cdot \nabla \partial_{\tau} p+\nabla \cdot(\hat{\rho} \nabla p) \frac{1}{2}|\nabla p|^{2}\right)\right\} \\
& =2 \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p-\nabla\left(\frac{1}{2}|\nabla p|^{2}\right)\right]+\int_{\partial \Omega} \hat{\rho} \nabla p \cdot \nu|\nabla p|^{2} \\
& \stackrel{(96)}{=} 2 \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p-\nabla\left(\frac{1}{2}|\nabla p|^{2}\right)\right] \\
& =2 \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p-\mathrm{D}^{2} p \cdot \nabla p\right]
\end{aligned}
$$

which mimics $\frac{d}{d \tau}\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}=2\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \frac{D}{d \tau} \operatorname{grad} F_{\mid \hat{\rho}}\right\rangle$. We now split $p$ into

$$
p=p_{1}+\alpha p_{2} \quad \text { where } \quad p_{1}(y)=e^{\prime}(\hat{\rho}(y)) \quad \text { and } \quad p_{2}(y)=\frac{1}{2}|y|^{2}
$$

that is, $p_{1} \cong \operatorname{grad} E_{\hat{\rho}}$ and $p_{2} \cong \operatorname{grad} M_{\mid \hat{\rho}}$. We will show that

$$
\begin{align*}
& -\int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p_{1}-\mathrm{D}^{2} p_{1} \cdot \nabla p\right] \\
& =\int_{\Omega}\left\{\left(\pi^{\prime}(\hat{\rho}) \hat{\rho}-\pi(\hat{\rho})\right)\left(\nabla^{2} p\right)^{2}+\pi(\hat{\rho}) \operatorname{tr}\left(\mathrm{D}^{2} p\right)^{2}\right\} \\
& \quad+\int_{\partial \Omega} \pi(\hat{\rho}) \nabla p \cdot I I \cdot \nabla p \tag{101}
\end{align*}
$$

where $v \cdot I I . v$ denotes the second fundamental form of $\partial \Omega$. This mimics

$$
-\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \frac{D}{d \tau} \operatorname{grad} E_{\mid \hat{\rho}}\right\rangle=\left\langle\operatorname{grad} F_{\hat{\rho}}, \operatorname{Hess} E_{\mid \hat{\rho}} \operatorname{grad} F_{\mid \hat{\rho}}\right\rangle,
$$

as can be seen from (83). On the other hand, it is obvious that

$$
\begin{equation*}
\int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p_{2}-\mathrm{D}^{2} p_{2} . \nabla p\right]=-\int_{\Omega} \hat{\rho}|\nabla p|^{2} \tag{102}
\end{equation*}
$$

which mimics

$$
\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \frac{D}{d \tau} \operatorname{grad} M_{\mid \hat{\rho}}\right\rangle=-\left\langle\operatorname{grad} F_{\mid \hat{\rho}}, \operatorname{Hess} M_{\mid \hat{\rho}} \operatorname{grad} F_{\mid \hat{\rho}}\right\rangle=-\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2},
$$

as can be seen from (84).
Let us establish the identity (101). For this, we write the first part of the integrand of the l. h. s. in (101) as follows:

$$
\begin{aligned}
& -\hat{\rho} \nabla p \cdot \nabla \partial_{\tau} p_{1} \\
& =\quad-\hat{\rho} \nabla p \cdot \nabla\left[e^{\prime \prime}(\hat{\rho}) \partial_{\tau} \hat{\rho}\right] \\
& \stackrel{(95)}{=}-\hat{\rho} \nabla p \cdot \nabla\left[e^{\prime \prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)\right] \\
& = \\
& =-\nabla p \cdot \nabla\left[\hat{\rho} e^{\prime \prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)\right]+\nabla p \cdot \nabla \hat{\rho} e^{\prime \prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p) \\
& \stackrel{(92)}{=} \\
& -\nabla p \cdot \nabla\left[\pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)\right]+\nabla p \cdot \nabla \hat{\rho} e^{\prime \prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p) .
\end{aligned}
$$

Thanks to the formula

$$
\begin{aligned}
\nabla \cdot\left[\nabla p \cdot \nabla p_{1} \hat{\rho} \nabla p\right]= & \nabla\left(\nabla p \cdot \nabla p_{1}\right) \cdot(\hat{\rho} \nabla p)+\nabla p \cdot \nabla p_{1} \nabla \cdot(\hat{\rho} \nabla p) \\
= & \hat{\rho} \nabla p \cdot \mathrm{D}^{2} p_{1} \cdot \nabla p+\hat{\rho} \nabla p_{1} \cdot \mathrm{D}^{2} p \cdot \nabla p \\
& +\nabla p \cdot \nabla p_{1} \nabla \cdot(\hat{\rho} \nabla p),
\end{aligned}
$$

which we rearrange to

$$
\begin{aligned}
\hat{\rho} \nabla p \cdot \mathrm{D}^{2} p_{1} \cdot \nabla p= & -\left\{\nabla p \cdot \nabla p_{1} \nabla \cdot(\hat{\rho} \nabla p)+\hat{\rho} \nabla p_{1} \cdot \mathrm{D}^{2} p \cdot \nabla p\right\} \\
& +\nabla \cdot\left[\nabla p \cdot \nabla p_{1} \hat{\rho} \nabla p\right],
\end{aligned}
$$

we have for the second part of the integral of the l. h. s. in (101):

$$
\int_{\Omega} \hat{\rho} \nabla p \cdot \mathrm{D}^{2} p_{1} \cdot \nabla p
$$

$$
\begin{aligned}
= & -\int_{\Omega}\left\{\nabla \cdot(\hat{\rho} \nabla p) \nabla p \cdot \nabla p_{1}+\hat{\rho} \nabla p_{1} \cdot \mathrm{D}^{2} p \cdot \nabla p\right\} \\
& +\int_{\partial \Omega} \nabla p \cdot \nabla p_{1} \hat{\rho} \nabla p \cdot \nu \\
\stackrel{(96)}{=} & -\int_{\Omega}\left\{\nabla \cdot(\hat{\rho} \nabla p) \nabla p \cdot \nabla p_{1}+\hat{\rho} \nabla p_{1} \cdot \mathrm{D}^{2} p \cdot \nabla p\right\}
\end{aligned}
$$

and rewrite the integrand as

$$
\begin{aligned}
& \nabla \cdot(\hat{\rho} \nabla p) \nabla p \cdot \nabla p_{1}+\hat{\rho} \nabla p_{1} \cdot \mathrm{D}^{2} p \cdot \nabla p \\
& \stackrel{(92)}{=} \nabla \cdot(\hat{\rho} \nabla p) e^{\prime \prime}(\hat{\rho}) \nabla p \cdot \nabla \hat{\rho}+\nabla[\pi(\hat{\rho})] \cdot \mathrm{D}^{2} p . \nabla p .
\end{aligned}
$$

Hence we obtain for the whole integral of the l. h. s. in (101):

$$
\begin{aligned}
& \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p_{1}+\mathrm{D}^{2} p_{1} \cdot \nabla p\right] \\
& \quad=-\int_{\Omega}\left\{\nabla p \cdot \nabla\left[\pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)\right]+\nabla[\pi(\hat{\rho})] \cdot \mathrm{D}^{2} p \cdot \nabla p\right\} .
\end{aligned}
$$

A further integration by parts yields

$$
\begin{align*}
\int_{\Omega} \hat{\rho} \nabla p \cdot & {\left[\nabla \partial_{\tau} p_{1}+\mathrm{D}^{2} p_{1} \cdot \nabla p\right] } \\
= & \int_{\Omega}\left\{\nabla^{2} p \pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)+\pi(\hat{\rho}) \nabla \cdot\left(\mathrm{D}^{2} p \cdot \nabla p\right)\right\} \\
& -\int_{\partial \Omega}\left\{\nabla p \cdot \nu \pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)+\pi(\hat{\rho}) \nu \cdot\left(\mathrm{D}^{2} p . \nabla p\right)\right\} \tag{103}
\end{align*}
$$

Let us consider the boundary integral in (103). The Neumann boundary condition (96) means that $\nabla p$ is a tangential vector field on $\partial \Omega$. Differentiating the Neumann boundary condition along this tangential vector field yields

$$
\begin{equation*}
\nu \cdot \mathrm{D}^{2} p \cdot \nabla p+\nabla p \cdot I I \cdot \nabla p=0 \quad \text { on } \partial \Omega . \tag{104}
\end{equation*}
$$

We use the identity (104) to substitute $\nu \cdot \mathrm{D}^{2} p . \nabla p$ in (103) and obtain

$$
\begin{align*}
& \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p_{1}+\mathrm{D}^{2} p_{1} \cdot \nabla p\right] \\
& = \\
& \quad \int_{\Omega}\left\{\nabla^{2} p \pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p)+\pi(\hat{\rho}) \nabla \cdot\left(\mathrm{D}^{2} p . \nabla p\right)\right\}  \tag{105}\\
& \quad+\int_{\partial \Omega} \pi(\hat{\rho}) \nabla p \cdot I I \cdot \nabla p
\end{align*}
$$

We reconsider the first part of the bulk integrand on the r. h. s. in (105):

$$
\begin{aligned}
\pi^{\prime}(\hat{\rho}) \nabla \cdot(\hat{\rho} \nabla p) \nabla^{2} p & =\pi^{\prime}(\hat{\rho}) \hat{\rho}\left(\nabla^{2} p\right)^{2}+\pi^{\prime}(\hat{\rho}) \nabla \hat{\rho} \cdot \nabla p \nabla^{2} p \\
& =\pi^{\prime}(\hat{\rho}) \hat{\rho}\left(\nabla^{2} p\right)^{2}+\nabla[\pi(\hat{\rho})] \cdot \nabla p \nabla^{2} p
\end{aligned}
$$

and perform a last integration by parts

$$
\begin{aligned}
& \int_{\Omega} \nabla[\pi(\hat{\rho})] \cdot \nabla p \nabla^{2} p \\
& \quad=\quad-\int_{\Omega} \pi(\hat{\rho}) \nabla \cdot\left(\nabla^{2} p \nabla p\right)+\int_{\partial \Omega} \pi(\hat{\rho}) \nu \cdot \nabla p \nabla^{2} p \\
& \quad \stackrel{(96)}{=}-\int_{\Omega} \pi(\hat{\rho}) \nabla \cdot\left(\nabla^{2} p \nabla p\right) .
\end{aligned}
$$

Hence we obtain

$$
\begin{aligned}
& \int_{\Omega} \hat{\rho} \nabla p \cdot\left[\nabla \partial_{\tau} p_{1}+\mathrm{D}^{2} p_{1} \cdot \nabla p\right] \\
&= \int_{\Omega}\left\{\pi^{\prime}(\hat{\rho}) \hat{\rho}\left(\nabla^{2} p\right)^{2}+\pi(\hat{\rho})\left[-\nabla \cdot\left(\nabla^{2} p \nabla p\right)+\nabla \cdot\left(\mathrm{D}^{2} p . \nabla p\right)\right]\right\} \\
&+\int_{\partial \Omega} \pi(\hat{\rho}) \nabla p \cdot I I \cdot \nabla p .
\end{aligned}
$$

We conclude the proof of identity (101) by evoking the formula

$$
-\nabla \cdot\left(\nabla^{2} p \nabla p\right)+\nabla \cdot\left(\mathrm{D}^{2} p \cdot \nabla p\right)=\operatorname{tr}\left(\mathrm{D}^{2} p\right)^{2}-\left(\nabla^{2} p\right)^{2}
$$

In order to conclude

$$
\frac{d}{d \tau} \int_{\Omega} \hat{\rho}|\nabla p|^{2} \leq-2 \alpha \int_{\Omega} \hat{\rho}|\nabla p|^{2}
$$

and thereby the proof of (98), it remains to show that the right hand side of (101) is non negative, that is: $\left\langle s, \operatorname{Hess} E_{\mid \hat{\rho}} s\right\rangle \geq 0$. Here we use our assumptions on $\pi$ and $\Omega$. The integral over $\Omega$ is non negative, since its integrand is non negative:

$$
\begin{aligned}
& \left(\pi^{\prime}(\hat{\rho}) \hat{\rho}-\pi(\hat{\rho})\right)\left(\nabla^{2} p\right)^{2}+\pi(\hat{\rho}) \operatorname{tr}\left(\mathrm{D}^{2} p\right)^{2} \\
& \stackrel{(93)}{\geq}\left(\pi^{\prime}(\hat{\rho}) \hat{\rho}-\pi(\hat{\rho})\right)\left(\nabla^{2} p\right)^{2}+\pi(\hat{\rho}) \frac{1}{N}\left(\nabla^{2} p\right)^{2} \\
& \stackrel{(93)}{\geq} 0,
\end{aligned}
$$

where we have used $\operatorname{tr} C^{2} \geq \frac{1}{N}(\operatorname{tr} C)^{2}$ for a symmetric $N \times N$-matrix $C$ as in (80) of subsection 4.4. The integral over $\partial \Omega$ is non negative since its integrand is non negative: Our assumption (93) on $\pi$ implies that the first factor $\pi(\hat{\rho})$ is non negative; the convexity of $\Omega$ implies that the second fundamental form $I I$ of $\partial \Omega$ is positive semi definite, hence also the second factor $\nabla p \cdot I I \cdot \nabla p$ is non negative.

Let us now tackle (100). Following the lines of subsection 3.5, we start by deriving an auxiliary result. Let $\hat{\rho}_{0}, \hat{\rho}_{1}$ be smooth and positive functions on $\bar{\Omega}$. We think of $\hat{\rho}_{i}(i=1,2)$ as being extended on $\mathbb{R}^{N}$ by zero so that according to (94),

$$
F\left(\hat{\rho}_{i}\right)=E\left(\hat{\rho}_{i}\right)+\alpha M\left(\hat{\rho}_{i}\right)=\int e\left(\hat{\rho}_{i}\right)+\alpha \int \hat{\rho}_{i} \frac{1}{2}|y|^{2} .
$$

Let $\mu$ denote an optimal transference plan in the definition of $d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}$. We consider $p_{i} \cong \operatorname{grad} F_{\mid \hat{\rho}_{i}}$, that is,

$$
p_{i}(y)=e^{\prime}\left(\hat{\rho}_{i}(y)\right)+\alpha \frac{1}{2}|y|^{2} .
$$

The auxiliary result states that

$$
\begin{equation*}
F\left(\hat{\rho}_{1}\right)-F\left(\hat{\rho}_{0}\right) \geq \int \nabla p_{0}\left(y_{0}\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(d y_{0} d y_{1}\right)+\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} \tag{106}
\end{equation*}
$$

The integral is well defined, since $p_{0}$ is smooth on $\bar{\Omega}$ and $\mu$ is supported on $\bar{\Omega} \times \bar{\Omega}$. In order to derive and interpret inequality (106), we need the curve $[0,1] \ni \sigma \mapsto \hat{\rho}_{\sigma}$ of least energy between $\hat{\rho}_{0}$ and $\hat{\rho}_{1}$. In this sense, (106) mimics (42) in subsection 3.5, that is,

$$
F\left(\hat{\rho}_{1}\right)-F\left(\hat{\rho}_{0}\right) \geq\left\langle\operatorname{grad} F_{\mid \hat{\rho}_{0}},\left.\frac{d \hat{\rho}}{d \sigma}\right|_{\mid \sigma=0}\right\rangle+\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} .
$$

In terms of $[0,1] \ni \sigma \mapsto \hat{\rho}_{\sigma}$, inequality (106) obviously is a consequence of

$$
\begin{equation*}
\frac{d^{+}}{d \sigma}{ }_{\mid \sigma=0} F\left(\hat{\rho}_{\sigma}\right) \geq \int \nabla p_{0}\left(y_{0}\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(d y_{0} d y_{1}\right) \tag{107}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{d^{2}}{d \sigma^{2}} F\left(\hat{\rho}_{\sigma}\right) \geq \alpha d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} \tag{108}
\end{equation*}
$$

The latter obviously splits into

$$
\begin{align*}
\frac{d^{2}}{d \sigma^{2}} E\left(\hat{\rho}_{\sigma}\right) & \geq 0 \quad \text { and }  \tag{109}\\
\frac{d^{2}}{d \sigma^{2}} M\left(\hat{\rho}_{\sigma}\right) & =d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} \tag{110}
\end{align*}
$$

For these statements to make sense, we need the existence of a (weak) curve $[0,1] \ni \sigma \mapsto \hat{\rho}_{\sigma}$ of least energy between $\hat{\rho}_{0}$ and $\hat{\rho}_{1}$. It is provided by results of McCann [6], which rely on earlier work by Brenier [3]. Let us state these results: According to Brenier [3], there exists a convex function $\varphi_{1}$ on $\mathbb{R}^{N}$ such that

$$
\begin{equation*}
\mu=\left(\operatorname{id} \times \nabla \varphi_{1}\right) \# \hat{\rho}_{0} \quad \text { and in particular } \quad \hat{\rho}_{1}=\nabla \varphi_{1} \# \hat{\rho}_{0} . \tag{111}
\end{equation*}
$$

According to McCann [6, Proposition 1.3 (ii)],

$$
\hat{\rho}_{\sigma}=\nabla \varphi_{\sigma} \# \hat{\rho}_{0} \quad \text { where } \quad \varphi_{\sigma}(y)=(1-\sigma) \frac{1}{2}|y|^{2}+\sigma \varphi_{1}(y)
$$

defines a non negative and integrable function $\hat{\rho}_{\sigma}$ on $\mathbb{R}^{N}$. A glance back to (75) in subsection 4.3 will convince the reader of our interpretation of $\sigma \mapsto \hat{\rho}_{\sigma}$ as a geodesic - which by construction is the curve of least energy between $\hat{\rho}_{0}$ and $\hat{\rho}_{1}$. We observe that in terms of $\mu$,

$$
\begin{equation*}
\int \hat{\rho}_{\sigma} \zeta=\int \zeta\left(\sigma y_{1}+(1-\sigma) y_{0}\right) \mu\left(d y_{0} d y_{1}\right) \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right) \tag{112}
\end{equation*}
$$

Furthermore, McCann shows in [6, Theorem 4.4] that the transformation formula (79) in subsection 4.4 can be made rigorous: For all $\sigma \in(0,1)$ we have

$$
\begin{equation*}
\int e\left(\hat{\rho}_{\sigma}(y)\right) d y=\int e\left(\frac{\hat{\rho}_{0}\left(y_{0}\right)}{\operatorname{det} \mathrm{D}^{2} \varphi_{\sigma}\left(y_{0}\right)}\right) \operatorname{det} \mathrm{D}^{2} \varphi_{\sigma}\left(y_{0}\right) d y_{0}, \tag{113}
\end{equation*}
$$

We recall that a convex function $\varphi$ has a gradient $\nabla \varphi$ and a $\operatorname{Hessian}^{2} \mathrm{D}^{2} \varphi$ in the sense that for almost every $y_{0}$,

$$
\begin{aligned}
& \varphi(y) \\
& \quad=\varphi\left(y_{0}\right)+\left(y-y_{0}\right) \cdot \nabla \varphi\left(y_{0}\right)+\left(y-y_{0}\right) \cdot \mathrm{D}^{2} \varphi\left(y_{0}\right) \cdot\left(y-y_{0}\right)+o\left(\left(y-y_{0}\right)^{2}\right) .
\end{aligned}
$$

A proof of this result of Alexandrov can be found in [9, Theorem A.2.]. The symmetric and positive semi definite matrix $\mathrm{D}^{2} \varphi_{\sigma}\left(y_{0}\right)$ in (113) is to be understood in this sense. We observe that $\mathrm{D}^{2} \varphi_{\sigma}\left(y_{0}\right)=\sigma \mathrm{D}^{2} \varphi\left(y_{0}\right)+(1-\sigma)$ id is positive definite for $\sigma<1$. Hence the division by $\operatorname{det} \mathrm{D}^{2} \varphi\left(y_{0}\right)$ in (113) causes no problem.

Let us start with (107). We note that our assumptions on $e$ and $\pi$ imply the convexity of $[0, \infty) \ni z \mapsto e(z)$. Indeed,

$$
z^{2} e^{\prime \prime}(z) \stackrel{(92)}{=} z \pi^{\prime}(z) \stackrel{(93)}{\geq} z\left(1-\frac{1}{N}\right) \pi(z) \stackrel{(93)}{\geq} 0 \quad \text { for all } z>0 .
$$

Therefore, we have

$$
e(z)-e\left(z_{0}\right) \geq e^{\prime}\left(z_{0}\right)\left(z-z_{0}\right) \quad \text { for all } z \geq 0 \text { and } z_{0}>0 .
$$

We thus obtain

$$
E\left(\hat{\rho}_{\sigma}\right)-E\left(\hat{\rho}_{0}\right) \geq \int e^{\prime}\left(\hat{\rho}_{0}\right)\left(\hat{\rho}_{\sigma}-\hat{\rho}_{0}\right) .
$$

Trivially,

$$
M\left(\hat{\rho}_{\sigma}\right)-M\left(\hat{\rho}_{0}\right)=\int \frac{1}{2}|y|^{2}\left(\hat{\rho}_{\sigma}(y)-\hat{\rho}_{0}(y)\right) d y
$$

so that by definition of $p_{0}$

$$
\begin{align*}
& \frac{1}{\sigma}\left(F\left(\hat{\rho}_{\sigma}\right)-F\left(\hat{\rho}_{0}\right)\right)  \tag{114}\\
& \geq \int p_{0} \frac{1}{\sigma}\left(\hat{\rho}_{\sigma}-\hat{\rho}_{0}\right) \\
& \stackrel{(112)}{=} \int \frac{1}{\sigma}\left(p_{0}\left(\sigma y_{1}+(1-\sigma) y_{0}\right)-p_{0}\left(y_{0}\right)\right) \mu\left(d y_{0} d y_{1}\right) . \tag{115}
\end{align*}
$$

We observe that 1.) the $\mu$-integral is supported on $\bar{\Omega} \times \bar{\Omega}, 2$.) for all $\left(y_{0}, y_{1}\right) \in$ $\bar{\Omega} \times \bar{\Omega}$ we have, as a consequence of the convexity of $\bar{\Omega}, \sigma y_{1}+(1-\sigma) y_{0} \in \bar{\Omega}$, 3.) $p_{0}$ is smooth in $\bar{\Omega}$. This implies that
$\lim _{\sigma \downarrow 0} \frac{1}{\sigma}\left(p_{0}\left(\sigma y_{1}+(1-\sigma) y_{0}\right)-p_{0}\left(y_{0}\right)\right)=\nabla p_{0}\left(y_{0}\right) \cdot\left(y_{1}-y_{0}\right)$
uniformly in $\left(y_{0}, y_{1}\right)$ in the support of $\mu$.

Therefore, the passage to the limit $\sigma \downarrow 0$ in the inequality (115) yields (107).
Convexity of $E$ along geodesics as expressed in (109) can be derived from the representation (113) by copying the arguments given in subsection 3.5. The argument for the strict convexity of $M$ along geodesics as quantified in (110) is simpler: According to (112),

$$
M\left(\hat{\rho}_{\sigma}\right)=\int \frac{1}{2}|y|^{2} \hat{\rho}_{\sigma}(y) d y=\int \frac{1}{2}\left|\sigma y_{1}+(1-\sigma) y_{0}\right|^{2} \mu\left(d y_{0}, d y_{1}\right)
$$

and therefore

$$
\frac{d^{2}}{d \sigma^{2}} M\left(\hat{\rho}_{\sigma}\right)=\int\left|y_{1}-y_{0}\right|^{2} \mu\left(d y_{0}, d y_{1}\right)=d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} .
$$

Now that we have established our auxiliary result (106), we observe that by symmetry, we also have

$$
\begin{equation*}
F\left(\hat{\rho}_{0}\right)-F\left(\hat{\rho}_{1}\right) \geq-\int \nabla p_{1}\left(y_{1}\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(d y_{0} d y_{1}\right)+\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} . \tag{116}
\end{equation*}
$$

Adding (106) and (116) yields

$$
\begin{equation*}
\int\left(\nabla p_{1}\left(y_{1}\right)-\nabla p_{0}\left(y_{0}\right)\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(d y_{0} d y_{1}\right) \geq \alpha d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} . \tag{117}
\end{equation*}
$$

Furthermore, we obtain from (106), dropping the $\alpha \frac{1}{2} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2}$-term,

$$
\begin{aligned}
& F\left(\hat{\rho}_{1}\right)-F\left(\hat{\rho}_{0}\right) \\
& \quad \geq \int \nabla p_{0}\left(y_{0}\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(d y_{0} d y_{1}\right) \\
& \quad \geq-\left(\int\left|\nabla p_{0}\left(y_{0}\right)\right|^{2} \mu\left(d y_{0} d y_{1}\right)\right)^{\frac{1}{2}}\left(\int\left|y_{1}-y_{0}\right|^{2} \mu\left(d y_{0} d y_{1}\right)\right)^{\frac{1}{2}} \\
& \quad=-\left(\int_{\Omega} \hat{\rho}_{0}\left|\nabla p_{0}\right|^{2}\right)^{\frac{1}{2}} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right),
\end{aligned}
$$

and thus by symmetry

$$
\begin{align*}
& \left|F\left(\hat{\rho}_{1}\right)-F\left(\hat{\rho}_{0}\right)\right| \\
& \quad \leq \max \left\{\left(\int_{\Omega} \hat{\rho}_{0}\left|\nabla p_{0}\right|^{2}\right)^{\frac{1}{2}},\left(\int_{\Omega} \hat{\rho}_{1}\left|\nabla p_{1}\right|^{2}\right)^{\frac{1}{2}}\right\} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right) . \tag{118}
\end{align*}
$$

We now are in the position to prove that for two smooth and positive solutions $\hat{\rho}_{0}$ and $\hat{\rho}_{1}$ of $(95,96)$ we have

$$
\begin{equation*}
\frac{d^{+}}{d \tau} d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} \leq-2 \alpha d\left(\hat{\rho}_{0}, \hat{\rho}_{1}\right)^{2} \tag{119}
\end{equation*}
$$

Since $\hat{\rho}_{0}(\tau)=\hat{\rho}_{*}$ defines a (stationary) smooth and positive solution of $(95,96)$, this proves (100). In order to prove (119), we consider the smooth velocity fields

$$
\begin{equation*}
u_{i}=-\nabla p_{i} \quad \text { where } \quad p_{i}(y)=e^{\prime}\left(\hat{\rho}_{i}(y)\right)+\alpha \frac{1}{2}|y|^{2} . \tag{120}
\end{equation*}
$$

Since $\hat{\rho}_{i}$ satisfies $(95,96)$, we have

$$
\begin{array}{rll}
\frac{\partial \hat{\rho}_{i}}{\partial \tau}+\nabla \cdot\left(\hat{\rho}_{i} u_{i}\right) & =0 & \text { in }[0, \infty) \times \Omega \\
u_{i} \cdot \nu & =0 & \text { on }[0, \infty) \times \partial \Omega
\end{array}
$$

Let us fix a time $\tau_{0}$ and show that the last two lines imply that

$$
\begin{align*}
& \left.\frac{d^{+}}{d \tau}\right|_{\mid \tau=\tau_{0}} d\left(\hat{\rho}_{0}(\tau), \hat{\rho}_{1}(\tau)\right)^{2} \\
& \quad \leq 2 \int\left(u_{1}\left(\tau_{0}, y_{1}\right)-u_{0}\left(\tau_{0}, y_{0}\right)\right) \cdot\left(y_{1}-y_{0}\right) \mu\left(\tau_{0}, d y_{0} d y_{1}\right) \tag{121}
\end{align*}
$$

where $\mu\left(\tau_{0}\right)$ is an optimal transference plan in the definition of the Wasserstein metric $d\left(\hat{\rho}_{0}\left(\tau_{0}\right), \hat{\rho}_{1}\left(\tau_{0}\right)\right)^{2}$. Obviously, (121) together with the definition (120) of the velocities and the inequality (117) imply (119). In order to prove (121), we observe that

$$
\frac{\partial \Phi_{i}}{\partial \tau}(\tau)=u_{i}(\tau) \circ \Phi_{i}(\tau) \quad \text { and } \quad \Phi_{i}\left(\tau_{0}\right)=\mathrm{id}
$$

defines a family $\left\{\Phi_{i}(\tau)\right\}_{\tau}$ of diffeomorphism of $\Omega$ which are such that for any $\tau \in[0, \infty]$

$$
\hat{\rho}_{i}(\tau)=\Phi_{i}(\tau) \# \hat{\rho}_{i}\left(\tau_{0}\right)
$$

Therefore,

$$
\mu(\tau)=\left(\Phi_{0}(\tau) \times \Phi_{1}(\tau)\right) \# \mu\left(\tau_{0}\right)
$$

defines an admissible transference plan in the definition of $d\left(\hat{\rho}_{0}(\tau), \hat{\rho}_{1}(\tau)\right)^{2}$ (observe that $\mu\left(\tau_{0}\right)$ is supported in $\bar{\Omega} \times \bar{\Omega}$, where $\Phi_{0}(\tau) \times \Phi_{1}(\tau)$ is defined). Hence for all $\tau>\tau_{0}$,

$$
\begin{align*}
& \frac{1}{\tau-\tau_{0}}\left(d\left(\hat{\rho}_{0}(\tau), \hat{\rho}_{1}(\tau)\right)^{2}-d\left(\hat{\rho}_{0}\left(\tau_{0}\right), \hat{\rho}_{1}\left(\tau_{0}\right)\right)^{2}\right) \\
& \leq \frac{1}{\tau-\tau_{0}}\left(\int\left|y_{1}-y_{0}\right|^{2} \mu\left(\tau, d y_{0} d y_{1}\right)-\int\left|y_{1}-y_{0}\right|^{2} \mu\left(\tau_{0}, d y_{0} d y_{1}\right)\right) \\
& \quad=\int \frac{1}{\tau-\tau_{0}}\left(\left|\Phi_{1}\left(\tau, y_{1}\right)-\Phi_{0}\left(\tau, y_{0}\right)\right|^{2}-\left|y_{1}-y_{0}\right|^{2}\right) \mu\left(\tau_{0}, d y_{0} d y_{1}\right) \tag{122}
\end{align*}
$$

We observe that by definition of $\Phi_{i}$

$$
\begin{aligned}
& \lim _{\tau \downarrow \tau_{0}} \frac{1}{\tau-\tau_{0}}\left(\left|\Phi_{1}\left(\tau, y_{1}\right)-\Phi_{0}\left(\tau, y_{0}\right)\right|^{2}-\left|y_{1}-y_{0}\right|^{2}\right) \\
& =2\left(u_{1}\left(\tau_{0}, y_{1}\right)-u_{0}\left(\tau_{0}, y_{0}\right)\right) \cdot\left(y_{1}-y_{0}\right) \\
& \quad \text { uniformly in }\left(y_{0}, y_{1}\right) \text { in the support of } \mu\left(\tau_{0}\right) .
\end{aligned}
$$

Therefore, the passage to the limit $\tau \downarrow \tau_{0}$ in the inequality (122) yields (121).
We finally address (99). As in our formal calculus in subsection 3.5, we need to know beforehand that

$$
\begin{equation*}
\lim _{\tau \uparrow \infty}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)=0 \tag{123}
\end{equation*}
$$

As in subsection 3.5, we obtain (123) from (98) and (100) in the weakened form of

$$
\lim _{\tau \uparrow \infty} \int_{\Omega} \hat{\rho}|\nabla p|^{2}=0 \quad \text { resp. } \quad \lim _{\tau \uparrow \infty} d\left(\hat{\rho}, \hat{\rho}^{*}\right)^{2}=0
$$

via the interpolation

$$
\left|F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right| \leq\left(\int_{\Omega} \hat{\rho}|\nabla p|^{2}\right)^{\frac{1}{2}} d\left(\hat{\rho}, \hat{\rho}_{*}\right)
$$

which follows from (118) and (97). The other ingredient is $\frac{d}{d \tau}(F(\hat{\rho})-$ $\left.F\left(\hat{\rho}_{*}\right)\right)=-\left|\operatorname{grad} F_{\mid \hat{\rho}}\right|^{2}$, that is,

$$
\frac{d}{d \tau}\left(F(\hat{\rho})-F\left(\hat{\rho}_{*}\right)\right)=\frac{d}{d \tau} F(\hat{\rho})
$$

$$
\begin{aligned}
& =\int_{\Omega} p \frac{\partial \rho}{\partial \tau} \\
& \stackrel{(95)}{=}-\int_{\Omega} p \nabla \cdot(\hat{\rho}(-\nabla p)) \\
& \stackrel{(96)}{=}-\int_{\Omega} \hat{\rho}|\nabla p|^{2}
\end{aligned}
$$

The rest of the argument follows the few corresponding lines in subsection 3.5.

### 5.5 Proof of the Theorem, part I

Deriving Theorem 1 from Proposition 1 is an uninspiring exercise in approximation arguments. For convenience, we set again

$$
\begin{aligned}
& e(z)=\left\{\begin{array}{cc}
\frac{1}{m-1} z^{m} & \text { for } m \neq 1 \\
z \ln z & \text { for } m=1
\end{array}\right\}, \\
& \pi(z)=z^{m}, \\
& \psi(z)=\frac{1}{m+1} z^{m+1}
\end{aligned}
$$

and observe that these functions are related by

$$
z e^{\prime \prime}(z)=\pi^{\prime}(z) \quad \text { and } \quad \psi^{\prime}(z)=\pi(z)
$$

We divide the statement of the theorem into two parts. The first part is to show that for a. e. $\tau_{0}$ and a. e. $\tau$ with $\tau>\tau_{0}$ we have

$$
\begin{align*}
& \exp (2 \alpha \tau) \int \frac{1}{\hat{\rho}(\tau)}|\nabla \pi(\hat{\rho}(\tau))+\alpha \hat{\rho}(\tau) y|^{2} \\
& \quad \leq \exp \left(2 \alpha \tau_{0}\right) \int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2},  \tag{124}\\
& \exp (2 \alpha \tau)\left\{\left(\int e(\hat{\rho}(\tau))+\alpha \int \hat{\rho}(\tau) \frac{1}{2}|y|^{2}\right)-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\} \\
& \quad \leq \exp \left(2 \alpha \tau_{0}\right)\left\{\left(\int e\left(\hat{\rho}_{0}\right)+\alpha \int \hat{\rho}_{0} \frac{1}{2}|y|^{2}\right)-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\} \\
& \quad \quad \text { for } m>1,  \tag{125}\\
& \exp (2 \alpha \tau) \int\left\{e(\hat{\rho}(\tau))-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}(\tau)-\hat{\rho}_{*}\right)\right\}
\end{align*}
$$

$$
\begin{align*}
& \leq \exp \left(2 \alpha \tau_{0}\right) \int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \\
& \text { for } m \leq 1,  \tag{126}\\
& \exp (2 \alpha \tau) d\left(\hat{\rho}(\tau), \hat{\rho}_{*}\right)^{2} \leq \exp \left(2 \alpha \tau_{0}\right) d\left(\hat{\rho}_{0}, \hat{\rho}_{*}\right)^{2}, \tag{127}
\end{align*}
$$

where $\hat{\rho}_{0}=\hat{\rho}\left(\tau_{0}\right)$. We start by observing that for a. e. $\tau_{0}=\ln \left(t_{0}\right)$ we have

$$
\begin{array}{r}
\int \hat{\rho}_{0}=1 \text { and } \int \psi\left(\rho_{0}\right)<\infty \\
\pi\left(\hat{\rho}_{0}\right) \in L_{l o c}^{1}\left(\mathbb{R}^{N}\right) \text { and } \nabla \pi\left(\hat{\rho}_{0}\right) \in L^{2}\left(\mathbb{R}^{N}\right),
\end{array}
$$

where $\rho_{0}=\rho\left(t_{0}\right)$. We fix such a $\tau_{0}=\ln \left(t_{0}\right)$. W. l. o. g. we may assume that the r. h. s. of (124), (125), (126) and (127) are finite, that is

$$
\begin{aligned}
\int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} & <\infty \\
\int e\left(\hat{\rho}_{0}\right) & <\infty \text { for } m>1, \\
\int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} & <\infty \text { for } m \leq 1, \\
\int \hat{\rho}_{0} \frac{1}{2}|y|^{2} & <\infty,
\end{aligned}
$$

the latter being a consequence of the assumption that $d\left(\hat{\rho}_{*}, \hat{\rho}_{0}\right)^{2}<\infty$ and the fact that $\int \hat{\rho}_{*} \frac{1}{2}|y|^{2}<\infty$.

We now approximate $\hat{\rho}_{0}$. We will construct functions $\hat{\rho}_{0, \nu}$ and $R_{\nu}<\infty$ such that

$$
\begin{aligned}
& \Omega_{\nu}=\left\{|y|<R_{\nu}\right\}, \\
& \hat{\rho}_{0, \nu} \text { is smooth and positive on } \bar{\Omega}_{\nu}
\end{aligned}
$$

with

$$
\begin{gather*}
\left\{\begin{array}{cc}
R_{\nu} & \xrightarrow{\hat{\rho}_{0, \nu}} \begin{array}{c}
\text { on } \Omega_{\nu} \\
0
\end{array} \text { else }^{\nu}
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \hat{\rho}_{0} \text { in } L^{1}\left(\mathbb{R}^{N}\right),  \tag{128}\\
\int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{0, \nu}}\left|\nabla \pi\left(\hat{\rho}_{0, \nu}\right)+\alpha \hat{\rho}_{0, \nu} y\right|^{2}  \tag{129}\\
\xrightarrow{\nu \uparrow \infty} \int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2},  \tag{130}\\
\int_{\Omega_{\nu}} e\left(\hat{\rho}_{0, \nu}\right) \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{0}\right) \text { for } m>1,
\end{gather*}
$$

$$
\begin{align*}
& \int_{\Omega_{\nu}}\left\{e\left(\hat{\rho}_{0, \nu}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \nu}-\hat{\rho}_{*}\right)\right\} \\
& \xrightarrow{\nu \uparrow \infty} \int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \quad \text { for } m \leq 1,  \tag{131}\\
& \quad \int_{\Omega_{\nu}} \hat{\rho}_{0, \nu} \frac{1}{2}|y|^{2} \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}_{0} \frac{1}{2}|y|^{2}, \tag{132}
\end{align*}
$$

and such that $\rho_{0, \nu}$ and $\check{\Omega}_{\nu}$ (defined by $\rho_{0, \nu}(t, x)=\frac{1}{t_{0}^{N \alpha}} \hat{\rho}_{0, \nu}\left(\frac{x}{t_{0}^{\alpha}}\right)$ and $\check{\Omega}_{\nu}=$ $t_{0}^{N \alpha} \Omega_{\nu}$ ) satisfy

$$
\begin{align*}
&\left\{\begin{array}{cc}
\rho_{0, \nu} & \text { on } \check{\Omega}_{\nu} \\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \rho_{0} \quad \text { in } L^{1}\left(\mathbb{R}^{N}\right),  \tag{133}\\
& \int_{\tilde{\Omega}_{\nu}} \psi\left(\rho_{0, \nu}\right) \xrightarrow{\nu \uparrow \infty} \int \psi\left(\rho_{0}\right) . \tag{134}
\end{align*}
$$

We construct $\hat{\rho}_{0, \nu}$ in three steps. The first step: For $R<\infty$ we set

$$
\Omega_{R}=\{|y|<R\}, \quad \check{\Omega}_{R}=\left\{|x|<t_{0}^{N \alpha} R\right\} .
$$

and observe that

$$
\begin{aligned}
& \left\{\begin{array}{cc}
\hat{\rho}_{0} & \text { on } \Omega_{R} \\
0 & \text { else }
\end{array}\right\} \xrightarrow{R \uparrow \infty} \hat{\rho}_{0} \quad \text { in } L^{1}\left(\mathbb{R}^{N}\right), \\
& \left\{\begin{array}{cc}
\rho_{0} & \text { on } \check{\Omega}_{R} \\
0 & \text { else }
\end{array}\right\} \xrightarrow{R \uparrow \infty} \rho_{0} \quad \text { in } L^{1}\left(\mathbb{R}^{N}\right) .
\end{aligned}
$$

By monotone convergence,

$$
\begin{aligned}
& \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} \xrightarrow{R \uparrow \infty} \int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} \\
& \int_{\Omega_{R}} e\left(\hat{\rho}_{0}\right) \xrightarrow{R \uparrow \infty} \int e\left(\hat{\rho}_{0}\right) \quad \text { for } m>1, \\
& \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \\
& \xrightarrow{R \uparrow \infty} \int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \quad \text { for } m \leq 1,
\end{aligned}
$$

$$
\begin{aligned}
\int_{\Omega_{R}} \hat{\rho}_{0} \frac{1}{2}|y|^{2} & \xrightarrow{R \uparrow \infty} \int \hat{\rho}_{0} \frac{1}{2}|y|^{2}, \\
\int_{\tilde{\Omega}_{R}} \psi\left(\rho_{0}\right) & \xrightarrow{R \uparrow \infty} \int \psi\left(\rho_{0}\right) .
\end{aligned}
$$

The second step: We fix $R<\infty$ an set for $\delta>0$

$$
\begin{aligned}
& \hat{\rho}_{0, \delta}=\min \left\{\max \left\{\hat{\rho}_{0}, \delta\right\}, \frac{1}{\delta}\right\} \quad \text { and hence } \\
& \rho_{0, \delta}=\min \left\{\max \left\{\rho_{0}, \frac{\delta}{t_{0}^{N \alpha}}\right\}, \frac{1}{\delta t_{0}^{N \alpha}}\right\} .
\end{aligned}
$$

Obviously

$$
\begin{array}{lll}
\hat{\rho}_{0, \delta} \xrightarrow{\delta \not \supset 0} \hat{\rho}_{0} & \text { in } L^{1}\left(\Omega_{R}\right), \\
\rho_{0, \delta} \xrightarrow{\delta \downarrow 0} \rho_{0} & \text { in } L^{1}\left(\check{\Omega}_{R}\right) .
\end{array}
$$

Since

$$
\nabla \pi\left(\hat{\rho}_{0, \delta}\right)=\left\{\begin{array}{cc}
\nabla \pi\left(\hat{\rho}_{0}\right) & \text { if } \hat{\rho}_{0} \in\left(\delta, \frac{1}{\delta}\right) \\
0 & \text { else }
\end{array}\right\}
$$

we have

$$
\frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)+\alpha \hat{\rho}_{0, \delta} y\right|^{2} \xrightarrow{\delta \downarrow 0} \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} \quad \text { a. e. in } \Omega_{R} .
$$

We also have for sufficiently small $\delta$

$$
\begin{aligned}
\frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)+\alpha \hat{\rho}_{0, \delta} y\right|^{2} & \leq \frac{2}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)\right|^{2}+2 \alpha^{2} \hat{\rho}_{0, \delta}|y|^{2} \\
& \leq \frac{2}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)\right|^{2}+2 \alpha^{2} \max \left\{\hat{\rho}_{0}, 1\right\}|y|^{2}
\end{aligned}
$$

with

$$
\begin{aligned}
& \left(\int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)\right|^{2}\right)^{\frac{1}{2}} \\
& \quad \leq\left(\int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2}\right)^{\frac{1}{2}}+\alpha\left(\int_{\Omega_{R}} \hat{\rho}_{0}|y|^{2}\right)^{\frac{1}{2}}<\infty \\
& \int_{\Omega_{R}} \max \left\{\hat{\rho}_{0}, 1\right\}|y|^{2}<\infty
\end{aligned}
$$

Therefore by dominated convergence

$$
\int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)+\alpha \hat{\rho}_{0, \delta} y\right|^{2} \xrightarrow{\delta \downarrow 0} \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} .
$$

In case of $m>1$ we have for $\delta \ll 1$

$$
0 \leq e\left(\hat{\rho}_{0, \delta}\right) \leq \max \left\{e\left(\hat{\rho}_{0}\right), 1\right\}
$$

Since $\max \left\{e\left(\hat{\rho}_{0}\right), 1\right\}$ is integrable on $\Omega_{R}$, we obtain by dominated convergence

$$
\int_{\Omega_{R}} e\left(\hat{\rho}_{0, \delta}\right) \xrightarrow{\delta \downarrow 0} \int_{\Omega_{R}} e\left(\hat{\rho}_{0}\right) .
$$

In case of $m \leq 1$, we observe that for

$$
z_{\delta}=\min \left\{\max \{z, \delta\}, \frac{1}{\delta}\right\} \quad \text { and } \quad \delta \leq z_{*} \leq \frac{1}{\delta}
$$

we have

$$
0 \leq e\left(z_{\delta}\right)-e\left(z_{*}\right)-e^{\prime}\left(z_{*}\right)\left(z_{\delta}-z_{*}\right) \leq e(z)-e\left(z_{*}\right)-e^{\prime}\left(z_{*}\right)\left(z-z_{*}\right) .
$$

Since

$$
\delta \leq \hat{\rho}_{*} \leq \frac{1}{\delta} \quad \text { on } \Omega_{R}
$$

for $\delta \ll 1$, we have

$$
\begin{aligned}
& \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0, \delta}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta}-\hat{\rho}_{*}\right)\right\} \\
& \quad \leq \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} .
\end{aligned}
$$

On the other hand, we have by Fatou's lemma

$$
\begin{aligned}
& \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \\
& \quad \leq \liminf _{\delta \downarrow 0} \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0, \delta}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta}-\hat{\rho}_{*}\right)\right\},
\end{aligned}
$$

so that we obtain

$$
\begin{aligned}
& \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0, \delta}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta}-\hat{\rho}_{*}\right)\right\} \\
& \stackrel{\delta \downarrow 0}{\longrightarrow} \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} .
\end{aligned}
$$

Finally, we have for $\delta \ll 1$

$$
0 \leq \psi\left(\rho_{0, \delta}\right) \leq \max \left\{\psi\left(\rho_{0}\right), 1\right\} .
$$

Since $\max \left\{\psi\left(\rho_{0}\right), 1\right\}$ is integrable on $\check{\Omega}_{R}$, we obtain by dominated convergence

$$
\int_{\tilde{\Omega}_{R}} \psi\left(\rho_{0, \delta}\right) \xrightarrow{\delta \downarrow 0} \int_{\tilde{\Omega}_{R}} \psi\left(\rho_{0}\right) .
$$

The third step: Fix $R<\infty$ and $\delta>0$. Since

$$
\begin{aligned}
\hat{\rho}_{0, \delta} \in\left[\delta, \frac{1}{\delta}\right] & \quad \text { on } \Omega_{R} \quad \text { and } \\
\int_{\Omega_{R}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)\right|^{2} & \leq \frac{1}{\delta} \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)\right|^{2} \\
& \leq \frac{2}{\delta} \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)+\alpha \hat{\rho}_{0, \delta} y\right|^{2}+\frac{2}{\delta} \alpha^{2} \int_{\Omega_{R}} \hat{\rho}_{0, \delta}|y|^{2} \\
& <\infty,
\end{aligned}
$$

there exists for $\epsilon>0$ a function $\hat{\rho}_{0, \delta, \epsilon}$ with

$$
\hat{\rho}_{0, \delta, \epsilon} \text { is smooth and }\left[\delta, \frac{1}{\delta}\right] \text {-valued on } \Omega_{R}
$$

and

$$
\begin{aligned}
\hat{\rho}_{0, \delta, \epsilon} & \xrightarrow{\epsilon \downarrow 0} \hat{\rho}_{0, \delta} \quad \text { in } L^{1}\left(\Omega_{R}\right), \\
\nabla \pi\left(\hat{\rho}_{0, \delta, \epsilon}\right) & \xrightarrow{\epsilon \downarrow 0} \nabla \pi\left(\hat{\rho}_{0, \delta}\right) \quad \text { in } L^{2}\left(\Omega_{R}\right) .
\end{aligned}
$$

This obviously implies

$$
\begin{aligned}
\int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta, \epsilon}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta, \epsilon}\right)+\alpha \hat{\rho}_{0, \delta, \epsilon} y\right|^{2} & \xrightarrow{\epsilon \downarrow 0} \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta}\right)+\alpha \hat{\rho}_{0, \delta} y\right|^{2} \\
\int_{\Omega_{R}} e\left(\hat{\rho}_{0, \delta, \epsilon}\right) & \xrightarrow{\epsilon \downarrow 0} \int_{\Omega_{R}} e\left(\hat{\rho}_{0, \delta}\right) \quad \text { for } m>1, \\
& \xrightarrow[\Omega_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0, \delta, \epsilon}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta, \epsilon}-\hat{\rho}_{*}\right)\right\}]{ } \int_{\Omega_{R}}\left\{e\left(\hat{\rho}_{0, \delta}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta}-\hat{\rho}_{*}\right)\right\} \quad \text { for } m \leq 1,
\end{aligned}
$$

$$
\int_{\Omega_{R}} \hat{\rho}_{0, \delta, \epsilon} \frac{1}{2}|y|^{2} \quad \xrightarrow{\epsilon \downarrow 0} \int_{\Omega_{R}} \hat{\rho}_{0, \delta} \frac{1}{2}|y|^{2},
$$

and

$$
\begin{aligned}
\rho_{0, \delta, \epsilon} & \stackrel{\epsilon \downarrow 0}{\longrightarrow} \rho_{0} \quad \text { in } L^{1}\left(\check{\Omega}_{R}\right), \\
\int_{\check{\Omega}_{R}} \psi\left(\rho_{0, \delta, \epsilon}\right) & \stackrel{\epsilon \downarrow 0}{\longrightarrow} \int_{\check{\Omega}_{R}} \psi\left(\rho_{0, \delta}\right)
\end{aligned}
$$

Collecting all these results, we obtain

$$
\begin{aligned}
& \lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0}\left\{\begin{array}{cc}
\hat{\rho}_{0, \delta, \epsilon} & \text { on } \Omega_{R} \\
0 & \text { else }
\end{array}\right\}=\hat{\rho}_{0} \quad \text { in } L^{1}\left(\mathbb{R}^{N}\right), \\
& \lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0} \int_{\Omega_{R}} \frac{1}{\hat{\rho}_{0, \delta, \epsilon}}\left|\nabla \pi\left(\hat{\rho}_{0, \delta, \epsilon}\right)+\alpha \hat{\rho}_{0, \delta, \epsilon} y\right|^{2}=\int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} \\
& \lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0} \int_{\Omega_{R}} e\left(\hat{\rho}_{0, \delta, \epsilon}\right)=\int e\left(\hat{\rho}_{0}\right) \quad \text { for } m>1, \\
& \lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0} \int\left\{e\left(\hat{\rho}_{0, \delta, \epsilon}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \delta, \epsilon}-\hat{\rho}_{*}\right)\right\} \\
&=\int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)\right\} \quad \text { for } m \leq 1, \\
& \lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0} \int_{\Omega_{R}} \hat{\rho}_{0, \delta, \epsilon} \frac{1}{2}|y|^{2}=\int \hat{\rho}_{0} \frac{1}{2}|y|^{2},
\end{aligned}
$$

and

$$
\begin{aligned}
\lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0}\left\{\begin{array}{cc}
\rho_{0, \delta, \epsilon} & \text { on } \check{\Omega}_{R} \\
0 & \text { else }
\end{array}\right\} & =\rho_{0} \quad \text { in } L^{1}\left(\mathbb{R}^{N}\right), \\
\lim _{R \uparrow \infty} \lim _{\delta \downarrow 0} \lim _{\epsilon \downarrow 0} \int_{\check{\Omega}_{R}} \psi\left(\rho_{0, \delta, \epsilon}\right) & =\int \psi\left(\rho_{0}\right) .
\end{aligned}
$$

Choosing appropriate sequences $R_{\nu} \xrightarrow{\nu \uparrow \infty} \infty, \delta_{\nu} \xrightarrow{\nu \uparrow \infty} 0$ and $\epsilon_{\nu} \xrightarrow{\nu \uparrow \infty} 0$ gives the desired $\Omega_{\nu}=\Omega_{R_{\nu}}$ and $\hat{\rho}_{0, \nu}=\hat{\rho}_{0, \delta_{\nu}, \epsilon_{\nu}}$.

We have to approximate $\pi$ in the degenerate case, that is, for $m>1$. We start by constructing a smooth $\pi_{1}$ with

$$
\left.\begin{array}{ccc}
\pi_{1}(z) & >0  \tag{135}\\
z \pi_{1}^{\prime}(z)-\left(1-\frac{1}{N}\right) \pi_{1}(z) & >0
\end{array}\right\} \quad \text { for all } z>0
$$

and

$$
\begin{array}{ll}
\pi_{1}^{\prime}=\text { const } & \text { on }\left[0, \frac{1}{2}\right] \\
\pi_{1}^{\prime}=\pi^{\prime} & \text { on }[2, \infty) \\
\pi_{1}^{\prime} \geq \pi^{\prime} & \text { on }[0, \infty)
\end{array}
$$

Indeed, consider

$$
\pi_{1}(z)=\left\{\begin{array}{cc}
m z & \text { for } z \leq 1 \\
z^{m}+(m-1) & \text { for } z \geq 1
\end{array}\right\},
$$

which is differentiable with

$$
\pi_{1}^{\prime}(z)=\left\{\begin{array}{cc}
m & \text { for } z \leq 1 \\
m z & \text { for } z \geq 1
\end{array}\right\}
$$

It is easy to check that this $\pi_{1}$ satisfies (135) and

$$
\begin{array}{lll}
\pi_{1}^{\prime}= & \text { const } & \text { on }[0,1] \\
\pi_{1}^{\prime}=\pi^{\prime} & \text { on }[1, \infty) \\
\pi_{1}^{\prime} \geq \pi^{\prime} & \text { on }[0, \infty)
\end{array}
$$

It remains to smoothen $\pi_{1}$ in a neighborhood of $z=1$. We now set

$$
\pi_{\delta}(z)=\delta^{m} \pi_{1}\left(\frac{z}{\delta}\right)
$$

Then we have by rescaling

$$
\left.\begin{array}{cc}
\pi_{\delta}(z) & >0  \tag{136}\\
z \pi_{\delta}^{\prime}(z)-\left(1-\frac{1}{N}\right) \pi_{\delta}(z) & >0
\end{array}\right\} \quad \text { for all } z>0
$$

and

$$
\left.\begin{array}{ccc}
\pi_{\delta}^{\prime}= & \text { const } & \text { on }\left[0, \frac{\delta}{2}\right]  \tag{137}\\
\pi_{\delta}^{\prime}= & \pi^{\prime} & \text { on }[2 \delta, \infty) \\
\pi_{\delta}^{\prime} \geq & \pi^{\prime} & \text { on }[0, \infty)
\end{array}\right\}
$$

while

$$
\begin{equation*}
\pi_{\delta} \xrightarrow{\delta \downarrow 0} \pi \quad \text { uniformly in }[0, \infty) . \tag{138}
\end{equation*}
$$

We define $e_{\delta}$ by

$$
\pi_{\delta}(z)=z e_{\delta}^{\prime}(z)-e_{\delta}(z)=z^{2} \frac{d}{d z}\left[\frac{1}{z} e_{\delta}(z)\right] \quad \text { and } \quad e_{\delta}^{\prime}(1)=e^{\prime}(1)
$$

and observe that this automatically implies

$$
\begin{equation*}
z e_{\delta}^{\prime \prime}(z)=\pi_{\delta}^{\prime}(z) \tag{139}
\end{equation*}
$$

and, thanks to the first line in (137),

$$
\lim _{z \downarrow 0} e_{\delta}^{\prime}(z)=-\infty \quad \text { and } \quad \lim _{z \downarrow 0} e_{\delta}(z)=0
$$

Since also $e(0)=0$, we infer that

$$
e_{\delta} \xrightarrow{\delta \downarrow 0} e \text { uniformly in }[0, \infty) .
$$

Since for fixed $\nu<\infty, \hat{\rho}_{0, \nu}$ is bounded away from zero on the bounded set $\Omega_{\nu}$, we have we may choose a sequence of positive numbers $\delta_{\nu} \xrightarrow{\nu \uparrow \infty} 0$ such that for $\left(\pi_{\nu}, e_{\nu}\right)=\left(\pi_{\delta_{\nu}}, e_{\delta_{\nu}}\right)$ we have

$$
\begin{align*}
\pi_{\nu}^{\prime}\left(\hat{\rho}_{0, \nu}\right) & =\pi^{\prime}\left(\hat{\rho}_{0, \nu}\right) \quad \text { on } \Omega_{\nu} \text { for } \nu \gg 1,  \tag{140}\\
\sup _{z \in(0, \infty)}\left|e_{\nu}(z)-e(z)\right|\left|\Omega_{\nu}\right| & \xrightarrow{\delta \downarrow 0} 0 . \tag{141}
\end{align*}
$$

Whenever it is notationally convenient, we write $\left(\pi_{\nu}, e_{\nu}\right)=(\pi, e)$ in the case of $m \leq 1$.

We now consider the solution of

$$
\begin{align*}
\frac{\partial \hat{\rho}_{\nu}}{\partial \tau}-\nabla^{2} \pi_{\nu}\left(\hat{\rho}_{\nu}\right)-\alpha \nabla \cdot\left(\hat{\rho}_{\nu} y\right) & =0 \quad \text { in }\left(\tau_{0}, \infty\right) \times \Omega_{\nu}  \tag{142}\\
\left(\nabla \pi_{\nu}\left(\hat{\rho}_{\nu}\right)+\alpha \hat{\rho}_{\nu} y\right) \cdot n & =0 \quad \text { on }\left(\tau_{0}, \infty\right) \times \partial \Omega_{\nu}  \tag{143}\\
\hat{\rho}_{\nu} & =\hat{\rho}_{0, \nu} \quad \text { on }\left\{\tau_{0}\right\} \times \Omega_{\nu} . \tag{144}
\end{align*}
$$

Since $\hat{\rho}_{0, \nu}$ is bounded on $\Omega_{\nu}$,

$$
\overline{\hat{\rho}}(\tau, y)=C \exp (\alpha \tau N)
$$

is a supersolution for $(142,143,144)$ for $C \gg 1$. Since $\hat{\rho}_{0, \nu}$ is bounded away from zero on $\Omega_{\nu}$,

$$
e_{\nu}^{\prime}(\underline{\hat{\rho}}(\tau, y))+\alpha \frac{1}{2}|y|^{2}=-C
$$

defines a subsolution for $(142,143,144)$ for $C \gg 1$. Since for both $m>1$ and $m \leq 1, \lim _{z \downarrow 0} e_{\nu}^{\prime}(z)=-\infty$, this subsolution is bounded away from 0 in $(-\infty, \infty) \times \Omega$. By the comparison principle for $(142,143), \hat{\rho}_{\nu}$ is bounded away from 0 and $\infty$ on bounded subsets of $(-\infty, \infty) \times \Omega$. Since in addition, $\hat{\rho}_{0, \nu}$ is smooth and positive on $\bar{\Omega}$, also $\hat{\rho}_{\nu}$ is smooth and positive on $(-\infty, \infty) \times \bar{\Omega}$ by standard linear parabolic theory. Hence, thanks to the relationship of $\pi_{\nu}$ and $e_{\nu}$ expressed in (139), $\hat{\rho}_{\nu}$ is a smooth and positive solution of

$$
\begin{array}{rll}
\frac{\partial \hat{\rho}_{\nu}}{\partial \tau}-\nabla \cdot\left(\hat{\rho}_{\nu} \nabla p_{\nu}\right) & =0 & \text { in }\left(\tau_{0}, \infty\right) \times \Omega_{\nu} \\
\hat{\rho}_{\nu} \nabla p_{\nu} \cdot n=0 & \text { on }\left(\tau_{0}, \infty\right) \times \partial \Omega_{\nu}
\end{array}
$$

where

$$
p_{\nu}=e_{\nu}^{\prime}\left(\hat{\rho}_{\nu}\right)+\alpha \frac{1}{2}|y|^{2} .
$$

Hence we may apply Proposition 1 and obtain

$$
\begin{gather*}
\frac{d}{d \tau}\left[\exp (2 \alpha \tau) \int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau)\left|\nabla p_{\nu}(\tau)\right|^{2}\right] \leq 0  \tag{145}\\
\frac{d}{d \tau}\left[\operatorname { e x p } ( 2 \alpha \tau ) \left(\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \frac{1}{2}|y|^{2}\right)\right.\right. \\
\left.\left.-\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right)\right] \leq 0  \tag{146}\\
\frac{d}{d \tau}\left[\exp (2 \alpha \tau) d\left(\hat{\rho}_{*, \nu}, \hat{\rho}_{\nu}(\tau)\right)^{2}\right] \leq 0
\end{gather*}
$$

where $\hat{\rho}_{*, \nu}$ is defined via

$$
e_{\nu}^{\prime}\left(\hat{\rho}_{*, \nu}(y)\right)+\alpha \frac{1}{2}|y|^{2}=\lambda \quad \text { and } \quad \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu}=\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}=\int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) .
$$

We again use the relationship between $e_{\nu}$ and $\pi_{\nu}$ in (139) to reexpress (145) and the definition of $\hat{\rho}_{*, \nu}$ to reexpress (146) (at least in case of $m \leq 1$ ): For all $\tau \in\left(\tau_{0}, \infty\right)$

$$
\begin{align*}
& \exp (2 \alpha \tau) \int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{\nu}(\tau)}\left|\nabla \pi_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \hat{\rho}_{\nu}(\tau) y\right|^{2} \\
& \quad \leq \exp \left(2 \alpha \tau_{0}\right) \int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{0, \nu}}\left|\nabla \pi_{\nu}\left(\hat{\rho}_{0, \nu}\right)+\alpha \hat{\rho}_{0, \nu} y\right|^{2} \tag{147}
\end{align*}
$$

$$
\begin{align*}
& \exp (2 \alpha \tau)\left\{\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \frac{1}{2}|y|^{2}\right)\right. \\
& - \\
& \left.\quad\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right\} \\
& \leq \exp \left(2 \alpha \tau_{0}\right)\left\{\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{0, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{0, \nu} \frac{1}{2}|y|^{2}\right)\right.  \tag{148}\\
& \left.\quad-\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right\} \text { for } m>1, \\
& \exp (2 \alpha \tau) \int_{\Omega_{\nu}}\left\{e_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)-e_{\nu}\left(\hat{\rho}_{*, \nu}\right)-e_{\nu}^{\prime}\left(\hat{\rho}_{*, \nu}\right)\left(\hat{\rho}_{\nu}(\tau)-\hat{\rho}_{*, \nu}\right)\right\} \\
& \leq \exp \left(2 \alpha \tau_{0}\right) \int_{\Omega_{\nu}}\left\{e_{\nu}\left(\hat{\rho}_{0, \nu}\right)-e_{\nu}\left(\hat{\rho}_{*, \nu}\right)-e_{\nu}^{\prime}\left(\hat{\rho}_{*, \nu}\right)\left(\hat{\rho}_{0, \nu}-\hat{\rho}_{*, \nu}\right)\right\}  \tag{149}\\
& \quad \operatorname{for} m \leq 1, \tag{150}
\end{align*}
$$

We will recover (124), (125), (126) and (127) from the above in the limit $\nu \uparrow \infty$.

The first goal is to identify the limit of $\hat{\rho}_{\nu}$ with $\hat{\rho}$. To this purpose, we consider the $\rho_{\nu}$ related to $\hat{\rho}_{\nu}$ via the usual transformation

$$
\rho_{\nu}(t, x)=\frac{1}{t^{N \alpha}} \hat{\rho}_{\nu}\left(\ln t, \frac{x}{t^{\alpha}}\right) .
$$

We now derive the energy estimate (in the traditional sense). From $(142,143)$ we infer the identity

$$
\frac{d}{d \tau} \int_{\Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right)=-\int_{\Omega_{\nu}} \nabla \psi^{\prime}\left(\hat{\rho}_{\nu}\right) \cdot\left(\nabla \pi_{\nu}\left(\hat{\rho}_{\nu}\right)+\alpha \hat{\rho}_{\nu} y\right)
$$

Since

$$
\begin{array}{cl}
\psi^{\prime \prime}(z) \pi_{\nu}^{\prime}(z) & \stackrel{(137)}{\geq} \psi^{\prime \prime}(z) \pi^{\prime}(z)=\left(\pi^{\prime}(z)\right)^{2} \\
z \psi^{\prime \prime}(z) & =m \psi^{\prime}(z)
\end{array}
$$

we obtain the inequality

$$
\begin{aligned}
& \frac{d}{d \tau} \int_{\Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right) \\
& \quad \leq-\int_{\Omega_{\nu}}\left\{\left|\nabla \pi\left(\hat{\rho}_{\nu}\right)\right|^{2}+\alpha m \nabla \psi\left(\hat{\rho}_{\nu}\right) \cdot y\right\}
\end{aligned}
$$

$$
\begin{aligned}
& =-\int_{\Omega_{\nu}}\left|\nabla \pi\left(\hat{\rho}_{\nu}\right)\right|^{2}+\alpha m N \int_{\Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right)-\alpha m \int_{\partial \Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right) y \cdot n \\
& \leq-\int_{\Omega_{\nu}}\left|\nabla \pi\left(\hat{\rho}_{\nu}\right)\right|^{2}+\alpha m N \int_{\Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right),
\end{aligned}
$$

where we have used in the last line that the integrand of the boundary integral is non negative (remember that $\Omega_{\nu}$ is a ball with center 0 ). We reformulate the inequality as

$$
\frac{d}{d \tau}\left[\exp (-\alpha m N \tau) \int_{\Omega_{\nu}} \psi\left(\hat{\rho}_{\nu}\right)\right]+\exp (-\alpha m N \tau) \int_{\Omega_{\nu}}\left|\nabla \pi\left(\hat{\rho}_{\nu}\right)\right|^{2} \leq 0
$$

which translates into the usual energy estimate

$$
\frac{d}{d t}\left[\int_{\tilde{\Omega}_{\nu}} \psi\left(\rho_{\nu}\right)\right]+\int_{\tilde{\Omega}_{\nu}}\left|\nabla \pi\left(\rho_{\nu}\right)\right|^{2} \leq 0
$$

where $\check{\Omega}_{\nu}=\check{\Omega}_{\nu}(t)=t^{N \alpha} \Omega_{\nu}$. Since $\int_{\tilde{\Omega}_{\nu}} \psi\left(\rho_{0, \nu}\right)$ is bounded for $\nu \uparrow \infty$ by construction of $\rho_{0, \nu}$ (see (134)), we have

$$
\begin{align*}
\sup _{t \in\left(t_{0}, \infty\right)} \int_{\tilde{\Omega}_{\nu}} \psi\left(\rho_{\nu}(t)\right) & \text { is bounded for } \nu \uparrow \infty  \tag{151}\\
\int_{t_{0}}^{\infty} \int_{\tilde{\Omega}_{\nu}}\left|\nabla \pi_{\nu}\left(\rho_{\nu}(t)\right)\right|^{2} d t & \text { is bounded for } \nu \uparrow \infty
\end{align*}
$$

Of course, $(142,144)$ translates into

$$
\begin{aligned}
\frac{\partial \rho_{\nu}}{\partial t}-\nabla^{2} \pi_{\nu}\left(\rho_{\nu}\right) & =0 \quad \text { in }\left(t_{0}, \infty\right) \times \check{\Omega}_{\nu} \\
\rho_{\nu} & =\rho_{0, \nu} \quad \text { on }\left\{t_{0}\right\} \times \check{\Omega}_{\nu} .
\end{aligned}
$$

Together with (133) and (138), we obtain by standard techniques for porousmedium type equations (see for instance [1])

$$
\left\{\begin{array}{cc}
\rho_{\nu} & \text { on }\left(t_{0}, \infty\right) \times \check{\Omega}_{\nu} \\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \rho \quad \text { in } L_{l o c}^{1}\left(\left(t_{0}, \infty\right) \times \mathbb{R}^{N}\right) .
$$

In particular we have for a. e. $\tau \in\left(\tau_{0}, \infty\right)$

$$
\left\{\begin{array}{cc}
\hat{\rho}_{\nu}(\tau) & \text { on } \check{\Omega}_{\nu}  \tag{152}\\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \hat{\rho}(\tau)\left\{\begin{array}{c}
\text { in } L_{l o c}^{1}\left(\mathbb{R}^{N}\right) \text { and } \\
\text { a. e. in } \mathbb{R}^{N} \text { for a subsequence }
\end{array}\right\} .
$$

We now pass to the limit in the inequalities $(147,148,149,150)$. We first investigate the convergence of $\hat{\rho}_{*, \nu}$ to $\hat{\rho}_{*}$. We consider the case of $m \leq 1$. According to (128) we have

$$
\begin{equation*}
\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu} \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}_{0}=1, \tag{153}
\end{equation*}
$$

so that $\hat{\rho}_{*, \nu}$ satisfies

$$
e^{\prime}\left(\hat{\rho}_{*, \nu}(y)\right)+\alpha \frac{1}{2}|y|^{2}=\lambda \quad \text { for } y \in \Omega_{\nu} \quad \text { and } \quad \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \xrightarrow{\nu \uparrow \infty} 1,
$$

whereas $\hat{\rho}_{*}$ is characterized by

$$
e^{\prime}\left(\hat{\rho}_{*}(y)\right)+\alpha \frac{1}{2}|y|^{2}=\lambda \quad \text { for } y \in \mathbb{R}^{N} \quad \text { and } \quad \int \hat{\rho}_{*}=1 .
$$

It is therefore a matter of elementary analysis to show

$$
\begin{align*}
&\left\{\begin{array}{cc}
\hat{\rho}_{*, \nu} & \text { on } \Omega_{\nu} \\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \hat{\rho}_{*}\left\{\begin{array}{c}
\text { in } L^{1}\left(\mathbb{R}^{N}\right) \text { and } \\
\text { a. e. in } \mathbb{R}^{N} \text { for a subsequence }
\end{array}\right\},  \tag{154}\\
& \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}_{*} \frac{1}{2}|y|^{2},  \tag{155}\\
& \lim _{\nu \uparrow \infty}\left\{\left(\int_{\Omega_{\nu}} e\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right.  \tag{156}\\
&\left.\quad\left(\int_{\Omega_{\nu}} e\left(\hat{\rho}_{*}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\}=0 \tag{157}
\end{align*}
$$

keeping in mind that $m>\frac{N}{N+2}$ ensures that $\int\left|e\left(\hat{\rho}_{*}\right)\right|, \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}<\infty$.
We now consider the case $m>1$. We observe that $\hat{\rho}_{*, \nu}$ and $\hat{\rho}_{*}$ are also characterized by

$$
\left.\begin{array}{l}
\hat{\rho}_{*, \nu} \operatorname{minimizes}  \tag{158}\\
\quad \int_{\Omega_{\nu}} e_{\nu}(\hat{\rho})+\alpha \int_{\Omega_{\nu}} \hat{\rho} \frac{1}{2}|y|^{2} \\
\text { among all } \hat{\rho} \geq 0 \text { with } \int_{\Omega_{\nu}} \hat{\rho}=\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}
\end{array}\right\}
$$

resp.

$$
\left.\begin{array}{l}
\hat{\rho}_{*} \text { minimizes }  \tag{159}\\
\qquad \int e(\hat{\rho})+\alpha \int \hat{\rho} \frac{1}{2}|y|^{2} \\
\text { among all } \hat{\rho} \geq 0 \text { with } \int \hat{\rho}=1
\end{array}\right\} .
$$

We will employ a variational argument to conclude

$$
\begin{align*}
\left.\begin{array}{cc}
\hat{\rho}_{*, \nu} & \text { on } \Omega_{\nu} \\
0 & \text { else }
\end{array}\right\} & \xrightarrow{\nu \uparrow \infty}  \tag{160}\\
\hat{\rho}_{*} & \text { in } L^{1}\left(\mathbb{R}^{N}\right),  \tag{161}\\
\int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} & \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}_{*} \frac{1}{2}|y|^{2},  \tag{162}\\
\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right) & \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{*}\right) .
\end{align*}
$$

Indeed, consider

$$
\hat{\rho}_{\nu}=a_{\nu} \hat{\rho}_{*} \quad \text { with } \quad a_{\nu}=\frac{\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}}{\int_{\Omega_{\nu}} \hat{\rho}_{*}},
$$

that is, $a_{\nu}$ is chosen such that $\hat{\rho}_{\nu}$ is admissible in (158). Hence

$$
\begin{equation*}
\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} \leq \int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{\nu} \frac{1}{2}|y|^{2} . \tag{163}
\end{equation*}
$$

We would now like to pass to the limit in the r. h. s. of (163). We start by observing that according to (153),

$$
\begin{equation*}
a_{\nu} \xrightarrow{\nu \uparrow \infty} 1 . \tag{164}
\end{equation*}
$$

According to (141), $\lim _{\nu \uparrow \infty} \int_{\Omega_{\nu}}\left|e_{\nu}\left(\hat{\rho}_{\nu}\right)-e\left(\hat{\rho}_{\nu}\right)\right|=0$; according to (164) and monotone convergence,

$$
\int_{\Omega_{\nu}} e\left(\hat{\rho}_{\nu}\right)=a_{\nu}^{m} \int_{\Omega_{\nu}} e\left(\hat{\rho}_{*}\right) \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{*}\right),
$$

so that

$$
\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}\right) \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{*}\right) .
$$

According to (164) and monotone convergence,

$$
\int_{\Omega_{\nu}} \hat{\rho}_{\nu} \frac{1}{2}|y|^{2}=a_{\nu} \int_{\Omega_{\nu}} \hat{\rho}_{*} \frac{1}{2}|y|^{2} \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}_{*} \frac{1}{2}|y|^{2} .
$$

Together we obtain

$$
\begin{equation*}
\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{\nu} \frac{1}{2}|y|^{2} \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2} . \tag{165}
\end{equation*}
$$

In particular, the r. h. s. of (163) is bounded, hence is the l. h. s.. This implies due to $e \geq 0$ and (141)

$$
\int_{\Omega_{\nu}} e\left(\hat{\rho}_{*, \nu}\right) \text { and } \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} \quad \text { are bounded for } \nu \uparrow \infty .
$$

Since $e$ has superlinear growth, there exists a $\hat{\rho}$ with

$$
\left\{\begin{array}{cc}
\hat{\rho}_{*, \nu} & \text { on } \Omega_{\nu}  \tag{166}\\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \hat{\rho} \quad \text { weakly in } L^{1}\left(\mathbb{R}^{N}\right),
$$

in particular by (153),

$$
\begin{equation*}
\int \hat{\rho}=\lim _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu}=\lim _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}=1 . \tag{167}
\end{equation*}
$$

According to (141), $\lim _{\nu \uparrow \infty} \int_{\Omega_{\nu}}\left|e_{\nu}\left(\hat{\rho}_{*, \nu}\right)-e\left(\hat{\rho}_{*, \nu}\right)\right|=0$; moreover, $e \geq 0$ is convex, so that (166) is sufficient to ensure

$$
\begin{equation*}
\int e(\hat{\rho}) \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right) . \tag{168}
\end{equation*}
$$

By monotone convergence and (166),

$$
\begin{align*}
\int \hat{\rho} \frac{1}{2}|y|^{2} & =\lim _{R \uparrow \infty} \int_{\{|y| \leq R\}} \hat{\rho} \frac{1}{2}|y|^{2} \\
& =\lim _{R \uparrow \infty} \lim _{\nu \uparrow \infty} \int_{\{|y| \leq R\}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} \\
& \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} . \tag{169}
\end{align*}
$$

Now by inequality (163) and the convergence expressed in (165), (168), (169),

$$
\int e(\hat{\rho})+\alpha \int \hat{\rho} \frac{1}{2}|y|^{2} \leq \int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2} .
$$

Line (167) ensures that $\hat{\rho}$ is admissible in (159) and thus also a minimizer. Since $e$ is strictly convex, the minimizers coincide

$$
\hat{\rho}=\hat{\rho}_{*},
$$

so that (168) and (169) turn into

$$
\begin{aligned}
\int e\left(\hat{\rho}_{*}\right) & \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right), \\
\int \hat{\rho}_{*} \frac{1}{2}|y|^{2} & \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2} .
\end{aligned}
$$

According to (163) and (165), we also have

$$
\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2} \geq \limsup _{\nu \uparrow \infty}\left(\int e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right) .
$$

This establishes (161) and (162). Thanks to the strict convexity of $e,(161)$ and (162) ensure that the weak convergence (166) turns into the desired strong convergence (160).

We now investigate the convergence of the r. h. s. of the inequalities (147), (148), (149) and (150). According to (140), (129) turns into

$$
\int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{0, \nu}}\left|\nabla \pi_{\nu}\left(\hat{\rho}_{0, \nu}\right)+\alpha \hat{\rho}_{0, \nu} y\right|^{2} \xrightarrow{\nu \uparrow \infty} \int \frac{1}{\hat{\rho}_{0}}\left|\nabla \pi\left(\hat{\rho}_{0}\right)+\alpha \hat{\rho}_{0} y\right|^{2} .
$$

Let us now consider the case of $m>1$. According to (141), (130) turns into

$$
\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{0, \nu}\right) \xrightarrow{\nu \uparrow \infty} \int e\left(\hat{\rho}_{0}\right) .
$$

Together with (132), (161) and (162), we obtain as desired

$$
\begin{aligned}
& \left\{\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{0, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{0, \nu} \frac{1}{2}|y|^{2}\right)-\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right\} \\
& \xrightarrow{\nu \uparrow \infty}\left\{\left(\int e\left(\hat{\rho}_{0}\right)+\alpha \int \hat{\rho}_{0} \frac{1}{2}|y|^{2}\right)-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\} .
\end{aligned}
$$

We now address the case of $m \leq 1$. By definition of $\hat{\rho}_{*, \nu}$ and $\hat{\rho}_{*}$ we have

$$
\begin{aligned}
&\left.\left(\int_{\Omega_{\nu}}\left\{e\left(\hat{\rho}_{0, \nu}\right)-e\left(\hat{\rho}_{*, \nu}\right)-e^{\prime}\left(\hat{\rho}_{*, \nu}\right)\left(\hat{\rho}_{0, \nu}\right)-\hat{\rho}_{*, \nu}\right)\right\}\right) \\
&\left.-\left(\int_{\Omega_{\nu}}\left\{e\left(\hat{\rho}_{0, \nu}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \nu}\right)-\hat{\rho}_{*}\right)\right\}\right) \\
&=\left(\int_{\Omega_{\nu}} e\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& -\left(\int_{\Omega_{\nu}} e\left(\hat{\rho}_{*}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right) \\
& +\lambda \int_{\Omega_{\nu}}\left(\hat{\rho}_{0, \nu}-\hat{\rho}_{*}\right) \\
(156),(128), \nu \uparrow \infty & \lambda \int\left(\hat{\rho}_{0}-\hat{\rho}_{*}\right)=0 .
\end{aligned}
$$

Hence (131) turns into

$$
\begin{aligned}
& \left.\int_{\Omega_{\nu}}\left\{e\left(\hat{\rho}_{0, \nu}\right)-e\left(\hat{\rho}_{*, \nu}\right)-e^{\prime}\left(\hat{\rho}_{*, \nu}\right)\left(\hat{\rho}_{0, \nu}\right)-\hat{\rho}_{*, \nu}\right)\right\} \\
& \left.\xrightarrow{\nu \uparrow \infty} \int\left\{e\left(\hat{\rho}_{0}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0}\right)-\hat{\rho}_{*}\right)\right\}
\end{aligned}
$$

Finally, since $\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}=\int_{\Omega_{\nu}} \hat{\rho}_{*, \nu}$ by construction of $\hat{\rho}_{*, \nu}$, (128), (132) resp. (154), (155) (for $m \leq 1$ ) or (160), (161) (for $m>1$ ) imply by Lemma 1

$$
d\left(\hat{\rho}_{*, \nu}, \hat{\rho}_{0, \nu}\right)^{2} \xrightarrow{\nu \uparrow \infty} d\left(\hat{\rho}_{*}, \hat{\rho}_{0}\right)^{2} .
$$

We finally address the convergence of the $1 . \mathrm{h}$. s. of the inequalities (147), (148), (149) and (150). This will be an exercise in lower semi-continuity arguments. Let us start by showing that for a. e. $\tau \in\left(\tau_{0}, \infty\right)$,

$$
\begin{equation*}
\int \frac{1}{\hat{\rho}(\tau)}|\nabla \pi(\hat{\rho}(\tau))+\alpha \hat{\rho}(\tau) y|^{2} \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{\nu}(\tau)}\left|\nabla \pi_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \hat{\rho}_{\nu}(\tau) y\right|^{2} . \tag{170}
\end{equation*}
$$

Because of the second statement in (152) and (138), we have pointwise almost everywhere convergence of $\pi_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)$ to $\pi(\hat{\rho}(\tau))$ for a subsequence. Since $\psi$ dominates $\pi_{\nu}$ uniformly in $\nu \uparrow \infty$, and the latter quantity is controlled according to (151), this pointwise almost everywhere convergence improves to

$$
\left\{\begin{array}{cc}
\pi\left(\hat{\rho}_{\nu}(\tau)\right) & \text { on } \Omega_{\nu}  \tag{171}\\
0 & \text { else }
\end{array}\right\} \xrightarrow{\nu \uparrow \infty} \pi(\hat{\rho}(\tau)) \quad \text { in } L_{\text {loc }}^{1}\left(\mathbb{R}^{N}\right)
$$

for a. e. $\tau \in\left(\tau_{0}, \infty\right)$. We set for convenience

$$
f_{\nu}(\tau)=\nabla \pi_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \hat{\rho}_{\nu}(\tau) y \quad \text { and } \quad f(\tau)=\nabla \pi(\hat{\rho}(\tau))+\alpha \hat{\rho}(\tau) y
$$

We restrict ourselves to one of the almost every $\tau$ with $f(\tau) \in L_{l o c}^{1}\left(\mathbb{R}^{N}\right)$ (keep in mind that our notion of weak solution presumes $\nabla \pi(\hat{\rho}) \in L_{l o c}^{1}((-\infty, \infty) \times$
$\left.\mathbb{R}^{N}\right)$ ). We observe that the first statement in (152) and (171) imply

$$
\begin{aligned}
\int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \zeta & \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}(\tau) \zeta \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right), \\
\int_{\Omega_{\nu}} f_{\nu}(\tau) \cdot \xi & \xrightarrow{\nu \uparrow \infty} \int f(\tau) \cdot \xi \quad \text { for all } \xi \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right) .
\end{aligned}
$$

It is obvious that this implies (170) in form of

$$
\int \frac{1}{\hat{\rho}(\tau)}|f(\tau)|^{2} \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \frac{1}{\hat{\rho}_{\nu}(\tau)}\left|f_{\nu}(\tau)\right|^{2}
$$

once we established the identity

$$
\begin{equation*}
\int \frac{1}{\rho} \frac{1}{2}|f|^{2}=\sup _{\xi \in C_{0}^{\infty}\left(\boldsymbol{R}^{N}\right)}\left\{\int f \cdot \xi-\int \rho \frac{1}{2}|\xi|^{2}\right\} \tag{172}
\end{equation*}
$$

which we claim is true for all non negative $\rho \in L_{l o c}^{1}\left(\mathbb{R}^{N}\right)$ and vector valued $f \in L_{l o c}^{1}\left(\mathbb{R}^{N}\right)$ with the understanding that

$$
\frac{1}{\rho} \frac{1}{2}|f|^{2}=\left\{\begin{array}{cl}
0 & \text { if } \rho=0 \text { and } f=0 \\
+\infty & \text { if } \rho=0 \text { and } f \neq 0
\end{array}\right\} .
$$

Let us now prove (172). The $\geq-$ part is an immediate consequence of the Cauchy-Schwarz inequality:

$$
\begin{aligned}
\int f \cdot \xi-\int \rho \frac{1}{2}|\xi|^{2} & \leq\left(\int \rho|\xi|^{2} \int \frac{1}{\rho}|f|^{2}\right)^{\frac{1}{2}}-\int \rho \frac{1}{2}|\xi|^{2} \\
& \leq \int \rho \frac{1}{2}|\xi|^{2}+\int \frac{1}{\rho} \frac{1}{2}|f|^{2}-\int \rho \frac{1}{2}|\xi|^{2} \\
& =\int \frac{1}{\rho} \frac{1}{2}|f|^{2} .
\end{aligned}
$$

The $\leq-$ part can be seen as follows: We would like to set $\xi=\frac{1}{\rho} f$ and hence need an approximation argument. For $R<\infty$, we consider

$$
\begin{aligned}
\rho_{R}(y) & =\left\{\begin{array}{cc}
\rho(y)+\frac{1}{R} & \text { if }|y| \leq R \\
0 & \text { else }
\end{array}\right\}, \\
f_{R}(y) & =\left\{\begin{array}{cc}
f(y) & \text { if }|f(y)| \leq R \text { and }|y| \leq R \\
0 & \text { else }
\end{array}\right\} .
\end{aligned}
$$

By monotone convergence, we have

$$
\int \frac{1}{\rho} \frac{1}{2}|f|^{2}=\lim _{R \uparrow \infty} \int_{\{|y| \leq R\}} \frac{\rho_{R}-\frac{1}{2} \rho}{\rho_{R}^{2}}\left|f_{R}\right|^{2} .
$$

Set

$$
\xi_{R}(y)=\left\{\begin{array}{cc}
\frac{1}{\rho_{R}(y)} f_{R}(y) & \text { if }|y| \leq R \\
0 & \text { else }
\end{array}\right\}
$$

and let $\xi_{R, \epsilon} \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right)$ be a mollification of $\xi_{R}$. For fixed $R<\infty$, the $\xi_{R, \epsilon}$ stay uniformly bounded, have uniformly bounded support and converge pointwise a. e. to $\xi_{R}$ for $\epsilon \downarrow 0$. We therefore have by dominated convergence

$$
\begin{aligned}
\lim _{\epsilon \downarrow 0}\left\{\int f \cdot \xi_{R, \epsilon}-\int \rho \frac{1}{2}\left|\xi_{R, \epsilon}\right|^{2}\right\} & =\int f \cdot \xi_{R}-\int \rho \frac{1}{2}\left|\xi_{R}\right|^{2} \\
& =\int_{\{|y| \leq R\}} f \cdot \frac{f_{R}}{\rho_{R}}-\int_{\{|y| \leq R\}} \rho \frac{1}{2}\left|\frac{f_{R}}{\rho_{R}}\right|^{2} \\
& =\int_{\{|y| \leq R\}} \frac{\rho_{R}-\frac{1}{2} \rho}{\rho_{R}^{2}}\left|f_{R}\right|^{2} .
\end{aligned}
$$

Putting both approximations together, we see

$$
\int \frac{1}{\rho} \frac{1}{2}|f|^{2}=\lim _{R \nmid \infty} \lim _{\epsilon \downarrow 0}\left\{\int f \cdot \xi_{R, \epsilon}-\int \rho \frac{1}{2}\left|\xi_{R, \epsilon}\right|^{2}\right\},
$$

which proves the $\leq-$ part in (172).
Let us now consider the case of $m>1$. Fix one of the almost all $\tau \in\left(\tau_{0}, \infty\right)$ with

$$
\begin{equation*}
\hat{\rho}_{\nu}(\tau) \xrightarrow{\nu \uparrow \infty} \hat{\rho}(\tau) \quad \text { a. e. in } \mathbb{R}^{N} . \tag{173}
\end{equation*}
$$

(the second statement in (152). Since $e \geq 0$ is continuous and thanks to (141), we obtain by Fatou's lemma

$$
\int e(\hat{\rho}(\tau)) \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right) .
$$

We immediately obtain from (173) and Fatou's lemma

$$
\int \hat{\rho}(\tau) \frac{1}{2}|y|^{2} \leq \liminf _{\nu \uparrow \infty} \int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \frac{1}{2}|y|^{2} .
$$

Together with (161) and (162), we obtain

$$
\begin{aligned}
& \left\{\left(\int e(\hat{\rho}(\tau))+\alpha \int \hat{\rho}(\tau) \frac{1}{2}|y|^{2}\right)\right. \\
& \left.\quad-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\} \\
& \quad \leq \liminf _{\nu \uparrow \infty}\left\{\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{\nu}(\tau)\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \frac{1}{2}|y|^{2}\right)\right. \\
& \left.\quad-\left(\int_{\Omega_{\nu}} e_{\nu}\left(\hat{\rho}_{*, \nu}\right)+\alpha \int_{\Omega_{\nu}} \hat{\rho}_{*, \nu} \frac{1}{2}|y|^{2}\right)\right\} .
\end{aligned}
$$

Now for the case of $m \leq 1$. Again, we fix one of the almost all $\tau \in\left(\tau_{0}, \infty\right)$ with

$$
\hat{\rho}_{\nu}(\tau) \xrightarrow{\nu \nmid \infty} \hat{\rho}(\tau) \quad \text { a. e. in } \mathbb{R}^{N} .
$$

Since we also have by (154)

$$
\hat{\rho}_{\nu, *} \xrightarrow{\nu \uparrow \infty} \hat{\rho}_{*}>0 \quad \text { a. e. in } \mathbb{R}^{N},
$$

we obtain from the continuity of $e$ on $[0, \infty)$ and the continuity of $e^{\prime}$ on $(0, \infty)$ that

$$
\begin{aligned}
& e\left(\hat{\rho}_{\nu}(\tau)\right)-e\left(\hat{\rho}_{\nu, *}\right)-e^{\prime}\left(\hat{\rho}_{\nu, *}\right)\left(\hat{\rho}_{\nu}(\tau)-\hat{\rho}_{\nu, *}\right) \\
& \stackrel{\nu \nmid \infty}{\longrightarrow} e(\hat{\rho}(\tau))-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}(\tau)-\hat{\rho}_{*}\right) \quad \text { a. e. in } \mathbb{R}^{N} .
\end{aligned}
$$

Since $e(z)-e\left(z_{*}\right)-e^{\prime}\left(z_{*}\right)\left(z-z_{*}\right) \geq 0$ by the convexity of $e$, we get by Fatou's lemma

$$
\begin{aligned}
& \int\left\{e(\hat{\rho}(\tau))-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}(\tau)-\hat{\rho}_{*}\right)\right\} \\
& \quad \leq \liminf _{\nu \uparrow \infty} \int\left\{e\left(\hat{\rho}_{\nu}(\tau)\right)-e\left(\hat{\rho}_{\nu, *}\right)-e^{\prime}\left(\hat{\rho}_{\nu, *}\right)\left(\hat{\rho}_{\nu}(\tau)-\hat{\rho}_{\nu, *}\right)\right\} .
\end{aligned}
$$

Finally, we observe that (152) implies that for a. e. $\tau \in\left(\tau_{0}, \infty\right)$

$$
\int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau) \zeta \xrightarrow{\nu \uparrow \infty} \int \hat{\rho}(\tau) \zeta \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right) .
$$

We recall that the evolution (142), (143) preserves mass:

$$
\int_{\Omega_{\nu}} \hat{\rho}_{\nu}(\tau)=\int_{\Omega_{\nu}} \hat{\rho}_{0, \nu}=\int_{\Omega_{\nu}} \hat{\rho}_{*, \nu},
$$

Together with (160) for $m>1$ resp. (154) for $m \leq 1$, this implies by Lemma 1 that

$$
d\left(\hat{\rho}(\tau), \hat{\rho}_{*}\right)^{2} \leq \liminf _{\nu \uparrow} d\left(\hat{\rho}_{\nu}(\tau), \hat{\rho}_{*, \nu}\right)^{2} .
$$

This achieves the passage to the limit $\nu \uparrow \infty$ in the l. h. s. of the inequalities (147,148,149,150) and thereby the proof of (124), (125), (126) and (127).

### 5.6 Proof of the Theorem, part II

The second part of the proof of the theorem is to show that for a. e. $\tau \in$ $(0, \infty)$,

$$
\begin{gather*}
\exp (2 \alpha \tau) \int \frac{1}{\hat{\rho}(\tau)}|\nabla \pi(\hat{\rho}(\tau))+\alpha \hat{\rho}(\tau) y|^{2} \leq \alpha^{2} \int \rho_{0}|x|^{2}  \tag{174}\\
\exp (2 \alpha \tau)\left\{\left(\int e(\hat{\rho}(\tau))+\alpha \int \hat{\rho}(\tau) \frac{1}{2}|y|^{2}\right)-\left(\int e\left(\hat{\rho}_{*}\right)+\alpha \int \hat{\rho}_{*} \frac{1}{2}|y|^{2}\right)\right\} \\
\leq \alpha \int \rho_{0} \frac{1}{2}|x|^{2} \quad \text { for } m>1  \tag{175}\\
\exp (2 \alpha \tau) \\
\leq\left\{e(\hat{\rho}(\tau))-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}(\tau)-\hat{\rho}_{*}\right)\right\}  \tag{176}\\
\exp (2 \alpha \tau) d\left(\hat{\rho}(\tau), \hat{\rho}_{*}\right)^{2} \leq \int \rho_{0} \frac{1}{2}|x|^{2} \quad \text { for } m \leq 1 \tag{177}
\end{gather*}
$$

To this purpose, we approximate the initial data $\rho$ by $\rho_{\nu}$ 's with the additional regularity expressed by

$$
\begin{aligned}
\int \frac{1}{\rho_{0, \nu}}\left|\nabla \pi\left(\rho_{0, \nu}\right)\right|^{2} & <\infty, \\
\int\left|e\left(\rho_{0, \nu}\right)\right| & <\infty,
\end{aligned}
$$

in the following sense

$$
\begin{align*}
\rho_{0, \nu} & \xrightarrow{\nu \uparrow \infty} \rho_{0} \text { in } L^{1}\left(\mathbb{R}^{N}\right) \text { and } \int \rho_{0, \nu}=\int \rho_{0},  \tag{178}\\
\int \psi\left(\rho_{0, \nu}\right) & \xrightarrow{\nu \uparrow \infty} \int \psi\left(\rho_{0}\right)<\infty,  \tag{179}\\
\int \rho_{0, \nu} \frac{1}{2}|x|^{2} & \xrightarrow{\nu \uparrow \infty} \int \rho_{0} \frac{1}{2}|x|^{2}<\infty .
\end{align*}
$$

This can be done in two steps: The first step is to mollify $\rho_{0}$ into a $\rho_{0, \epsilon}$. The second step consists in passing to

$$
\rho_{0, \epsilon, \delta}=a_{\epsilon, \delta} \max \left\{\rho_{0, \epsilon}, \delta \rho_{*}\right\},
$$

where $\rho_{*}$ denotes a fixed smooth and positive function with $\int \frac{1}{\rho_{*}}\left|\nabla \pi\left(\rho_{*}\right)\right|^{2}<$ $\infty, \int\left|e\left(\rho_{*}\right)\right|<\infty, \int \rho_{*} \frac{1}{2}|x|^{2}<\infty$ and $\int \psi\left(\rho_{*}\right)<\infty$, and $a_{\epsilon, \delta}$ is choosen such that $\int \rho_{0, \epsilon, \delta}=1$. This time, we leave the details to the reader.

Now for $\delta>0$, let $\rho_{\nu}^{(\delta)}$ denote the solution of the porous medium equation (in the sense of Definition 1) for $t \geq \delta$ with $\rho_{\nu}^{(\delta)}(\delta)=\rho_{0, \nu}$. Let $\hat{\rho}_{\nu}^{(\delta)}$ and $\hat{\rho}_{0, \nu}^{(\delta)}$ be related to $\rho_{\nu}^{(\delta)}$ and $\rho_{0, \nu}$ via the usual transformation. By the first part of this proof we have for a. e. $\tau \in(\ln \delta, \infty)$

$$
\begin{gather*}
\exp (2 \alpha \tau) \int \frac{1}{\hat{\rho}_{\nu}^{(\delta)}(\tau)}\left|\nabla \pi\left(\hat{\rho}_{\nu}^{(\delta)}(\tau)\right)+\alpha \hat{\rho}_{\nu}^{(\delta)}(\tau) y\right|^{2} \\
\leq \exp (2 \alpha \ln \delta) \int \frac{1}{\hat{\rho}_{0, \nu}^{(\delta)}}\left|\nabla \pi\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)+\alpha \hat{\rho}_{0, \nu}^{(\delta)} y\right|^{2},  \tag{180}\\
\exp (2 \alpha \tau)\left\{\left(\int e\left(\hat{\rho}_{\nu}^{(\delta)}(\tau)\right)+\alpha \int \hat{\rho}_{\nu}^{(\delta)}(\tau) \frac{1}{2}|y|^{2}\right)-F\left(\hat{\rho}_{*}\right)\right\} \\
\leq \exp (2 \alpha \ln \delta)\left\{\left(\int e\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)+\alpha \int \hat{\rho}_{0, \nu}^{(\delta)} \frac{1}{2}|y|^{2}\right)-F\left(\hat{\rho}_{*}\right)\right\} \\
\quad \text { for } m>1,  \tag{181}\\
\exp (2 \alpha \tau) \int\left\{e\left(\hat{\rho}_{\nu}^{(\delta)}(\tau)\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{\nu}^{(\delta)}(\tau)-\hat{\rho}_{*}\right)\right\} \\
\leq \exp (2 \alpha \ln \delta) \int\left\{e\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \nu}^{(\delta)}-\hat{\rho}_{*}\right)\right\} \\
\quad \text { for } m \leq 1,  \tag{182}\\
\exp (2 \alpha \tau) d\left(\hat{\rho}_{\nu}^{(\delta)}(\tau), \hat{\rho}_{*}\right)^{2} \leq \exp (2 \alpha \ln \delta) d\left(\hat{\rho}_{0, \nu}^{(\delta)}, \hat{\rho}_{*}\right)^{2}, \tag{183}
\end{gather*}
$$

We pass first to the limit $\delta \downarrow 0$ and then to the limit $\nu \uparrow \infty$. We consider the right hand side of (180), (181), (182) and (183) first. Our strategy is to express these terms in terms of $\rho_{0, \nu}$ and then pass to the limits. We obtain

$$
\exp (2 \alpha \ln \delta) \int \frac{1}{\hat{\rho}_{0, \nu}^{(\delta)}}\left|\nabla \pi\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)+\alpha \hat{\rho}_{0, \nu}^{(\delta)} y\right|^{2}
$$

$$
\begin{aligned}
& =\int \frac{1}{\rho_{0, \nu}}\left|\delta \nabla \pi\left(\rho_{0, \nu}\right)+\alpha \rho_{0, \nu} x\right|^{2} \\
& \xrightarrow{\delta \downarrow 0} \alpha^{2} \int \rho_{0, \nu}|x|^{2} \quad \text { for fixed } \nu<\infty \\
& \xrightarrow{\nu \uparrow \infty} \alpha^{2} \int \rho_{0}|x|^{2} .
\end{aligned}
$$

In case of $m>1$, we have

$$
\begin{aligned}
& \exp (2 \alpha \ln \delta)\left\{\left(\int e\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)+\alpha \int \hat{\rho}_{0, \nu}^{(\delta)} \frac{1}{2}|y|^{2}\right)-F\left(\hat{\rho}_{*}\right)\right\} \\
& \quad=\quad \delta \int e\left(\rho_{0, \nu}\right)+\alpha \int \rho_{0, \nu} \frac{1}{2}|x|^{2}-\delta^{2 \alpha} F\left(\hat{\rho}_{*}\right) \\
& \xrightarrow{\delta \downarrow 0} \alpha \int \rho_{0, \nu} \frac{1}{2}|x|^{2} \quad \text { for fixed } \nu<\infty \\
& \xrightarrow{\nu \dashv \infty} \alpha \int \rho_{0} \frac{1}{2}|x|^{2} .
\end{aligned}
$$

In case of $m \leq 1$, we have by definition of $\hat{\rho}_{*}$

$$
\begin{aligned}
& \int\left\{e\left(\hat{\rho}_{0, \nu}^{(\delta)}\right)-e\left(\hat{\rho}_{*}\right)-e^{\prime}\left(\hat{\rho}_{*}\right)\left(\hat{\rho}_{0, \nu}^{(\delta)}-\hat{\rho}_{*}\right)\right\} \\
& =\left(\int e\left(\hat{\rho}_{\nu}^{(\delta)}(\tau)\right)+\alpha \int \hat{\rho}_{\nu}^{(\delta)}(\tau) \frac{1}{2}|y|^{2}\right)-F\left(\hat{\rho}_{*}\right),
\end{aligned}
$$

and then the same argument as in the case $m>1$ applies. Finally,

$$
\exp (2 \alpha \ln \delta) d\left(\hat{\rho}_{0, \nu}^{(\delta)}, \hat{\rho}_{*}\right)^{2}=d\left(\hat{\rho}_{0, \nu}, \rho_{*}(\delta)\right)^{2}
$$

where $\rho_{*}(\delta, x)=\frac{1}{\delta^{N \alpha}} \hat{\rho}_{*}\left(\frac{x}{\delta^{\alpha}}\right)$. Since $\rho_{*}(\delta)$ converges to the Dirac measure at the origin, $\mu_{0}$, in the sense of

$$
\begin{aligned}
\int \rho_{*}(\delta) \zeta & \xrightarrow{\delta \downarrow 0} \int \zeta d \mu_{0} \quad \text { for all } \zeta \in C_{0}^{\infty}\left(\mathbb{R}^{N}\right), \\
\int \rho_{*}(\delta) \frac{1}{2}|x|^{2} & \xrightarrow{\delta \downarrow 0} \int \frac{1}{2}|x|^{2} d \mu_{0},
\end{aligned}
$$

we obtain by Lemma 1 that

$$
d\left(\hat{\rho}_{0, \nu}, \rho_{*}(\delta)\right)^{2} \quad \xrightarrow{\delta \downarrow 0} d\left(\hat{\rho}_{0, \nu}, \mu_{0}\right)^{2} .
$$

It follows immediately from Definition 2 that

$$
d\left(\hat{\rho}_{0, \nu}, \mu_{0}\right)^{2}=\int \rho_{0, \nu}|x|^{2}
$$

so that also here we obtain

$$
\left.\lim _{\nu \uparrow \infty} \lim _{\delta \downarrow 0} \exp (2 \alpha \ln \delta) d\left(\hat{\rho}_{0, \nu}^{(\delta)}\right), \hat{\rho}_{*}\right)^{2}=\int \rho_{0}|x|^{2} .
$$

Altogether, we see that the r. h. s. of (180), (181), (182) and (183) converge to the r. h. s. of (174), (175), (176) and (177).

We now consider the $1 . \mathrm{h}$. s. of the inequalities (180), (181), (182) and (183) in the limit $\nu \uparrow \infty$ and $\delta \downarrow 0$. From (178) and (179), one can deduce by standard techniques for the porous-medium type equations (see for instance [1]), that

$$
\lim _{\substack{\nu \uparrow \infty \\ \delta \downarrow 0}} \rho_{\nu}^{(\delta)}=\rho \quad \text { in } L^{1}\left((0, \infty) \times \mathbb{R}^{N}\right),
$$

with no restriction on the relation between $\delta$ and $\nu$. By the lower semicontinuity arguments from the first part of the proof we see the l. h. s. of (174), (175), (176) and (177) are estimated by the limes superior of the l. h. s. of (180), (181), (182) and (183). This achieves the second part of the proof, that is, the proof of (174), (175), (176) and (177).

## 6 Acknowledgments

The author's PhD advisor, Stephan Luckhaus, always stressed the importance of underlying gradient flow structures. David Kinderlehrer is coauthor on an earlier paper on the relationship between diffusion equations and the Wasserstein metric, this paper owes to many conversations with him. The idea of using Riemannian calculus to derive contraction properties for partial differential equations developed in conversations with Robert McCann in 1997 and later with Cedric Villani in 1998. The author gave a lecture series on the results of this paper in 1998 at the Max-Planck Institute for Mathematics in the Sciences in Leipzig, and wishes to thank the Institute for this opportunity.
