# Random attractors for dissipative systems with rough noises 

Luu Hoang Duc *

#### Abstract

We provide an analytic approach to study the asymptotic dynamics of rough differential equations, with the driving noises of Hölder continuity. Such systems can be solved with Lyons' theory of rough paths, in particular the rough integrals are understood in the Gubinelli sense for controlled rough paths. Using the framework of random dynamical systems and random attractors, we prove the existence and upper semi-continuity of the global pullback attractor for dissipative systems perturbed by bounded noises. Moreover, if the unperturbed system is strictly dissipative then the random attractor is a singleton for sufficiently small noise intensity.

Keywords: stochastic differential equations (SDE), rough path theory, rough integrals, random dynamical systems, random attractors, stochastic perturbation, stochastic stability.

## 1 Introduction

This paper studies the asymptotic behavior of the stochastic differential equation

$$
\begin{equation*}
d y_{t}=f\left(y_{t}\right) d t+g\left(y_{t}\right) d X_{t} \tag{1.1}
\end{equation*}
$$

where $f: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}, g: \mathbb{R}^{d} \rightarrow \mathcal{L}\left(\mathbb{R}^{m}, \mathbb{R}^{d}\right)$ are of enough regularity, and $X_{t} \in \mathbb{R}^{m}$ is a stochastic process with stationary increments, such that almost sure all realizations are $\nu$-Hölder continuous for some $\nu \in\left(\frac{1}{3}, 1\right)$ and $d, m \in \mathbb{N}$ (e.g. fractional Brownian motions [32] with Hurst indices $H \in$ $\left.\left(\frac{1}{3}, 1\right)\right)$. It is well known that such equation can be solved by using Lyons' theory of rough paths (see [30], [31] and also [14]), namely one attempts to solve the controlled differential equation

$$
\begin{equation*}
d y_{t}=f\left(y_{t}\right) d t+g\left(y_{t}\right) d x_{t} \tag{1.2}
\end{equation*}
$$

for the driving path $x$ to be a realization of $X$ in the space $C^{\nu}\left(\mathbb{R}, \mathbb{R}^{m}\right)$ of continuous paths with finite $\nu$ - Hölder norm on any finite time interval, such that $x$ can be lifted to a rough path $\mathbf{x}=(x, \mathbb{X})$. The solution of (1.2) is often understood in the sense of either Lyons-Davie [30], [31], or of Friz-Victoir [14], [35], which needs not to specify rough integrals. On the other hand, equation (1.2) can also be understood in the integral form

$$
\begin{equation*}
y_{t}=y_{0}+\int_{0}^{t} f\left(y_{s}\right) d s+\int_{0}^{t} g\left(y_{s}\right) d x_{s}, \quad \forall t \geq 0 \tag{1.3}
\end{equation*}
$$

where the second integral is a rough integral for controlled rough paths in the sense of Gubinelli [17]. As such, system (1.3) is recently proved in [10] to admit a unique path-wise solution given the initial condition. An alternative approach is to define rough integrals using fractional calculus, as studied for example in [25], [16], [24].

Our aim is to investigate the role of the driving noise in the longterm behavior of system (1.1). This question is studied in a probabilistic approach in the series [18], [19], [20], [21], in which they

[^0]prove that, under the dissipativity and some additional regularity conditions there exists a unique adapted stationary solution for (1.1) in the sense that the generated stochastic dynamical system over a stationary noise process has a unique invariant probability measure [19]. Moreover, the convergence is of probability type, i.e. other probability measures converge to the unique invariant measure in the total variation norm.

In this paper, we propose an analytic approach to study the stochastic perturbation problem. Namely we impose assumptions for the drift coefficient so that there exists a global attractor for the deterministic system

$$
\begin{equation*}
\dot{\mu}=f(\mu) \tag{1.4}
\end{equation*}
$$

which is asymptotically stable, and then raise the questions on the asymptotic dynamics of the perturbed system (1.1), in particular the existence of stationary states and their asymptotic (stochastic) stability with respect to almost sure convergence.

Note that the classical methods [36], [26], [33] on stochastic stability depends crucially on the nature of Itô calculus, since one can take advantage of the martingale property of the noise to apply Ito's formula for a Lyapunov function and then take the expectation to eliminate the noise part. As a result, the expectation of the solution norm can be proved to decay exponentially to zero, which is enough to prove that the solution norm itself converges exponentially and almost surely to zero due to Borel-Catelli lemma. The situation is however different here with a general noise $Z$, which is neither a Markov process nor a semimartingale (e.g. fractional Brownian motion $B^{H}$ [34]), hence the noise part does not vanish by taking the expectation. This challenge suggests that a new approach to study stochastic stability is necessary.

Results in [15] and recently in [2], [11], [12], [7] suggest that the above questions could be studied in the framework of random dynamical systems [1], hence asymptotic structures like random attractors are well-understood. In this scenarios, system (1.1) has no deterministic equilibrium but is expected to possess a random attractor, although little is known on the inside structure of the attractor and much less on whether or not the attractor is a (random) singleton.

## Assumptions and main results

Throughout the paper, we will assume that.
$\left(\mathbf{H}_{f}\right) f$ is locally Lipschitz continuous and dissipative, i.e. there exist constants $D_{1} \geq 0, D_{2}>0$ such that

$$
\begin{equation*}
\langle y, f(y)\rangle \leq\|y\|\left(D_{1}-D_{2}\|y\|\right), \quad \forall y \in \mathbb{R}^{d} ; \tag{1.5}
\end{equation*}
$$

in addition $f$ is of linear growth in the perpendicular direction, i.e. there exists $C_{f}>0$ such that

$$
\begin{equation*}
\left\|f(y)-\frac{\langle f(y), y\rangle}{\|y\|^{2}} y\right\| \leq C_{f}(1+\|y\|), \quad \forall y \neq 0 \tag{1.6}
\end{equation*}
$$

$\left(\mathbf{H}_{g}\right) g$ belongs to $C_{b}^{3}\left(\mathbb{R}^{d}, \mathcal{L}\left(\mathbb{R}^{m}, \mathbb{R}^{d}\right)\right)$ such that

$$
\begin{equation*}
C_{g}:=\max \left\{\|g\|_{\infty},\|D g\|_{\infty},\left\|D_{g}^{2}\right\|_{\infty},\left\|D_{g}^{3}\right\|_{\infty}\right\}<\infty ; \tag{1.7}
\end{equation*}
$$

$\left(\mathbf{H}_{X}\right)$ for a given $\nu \in\left(\frac{1}{3}, \frac{1}{2}\right), x$ belongs to the space $C^{\nu}\left(\mathbb{R}, \mathbb{R}^{m}\right)$ of all continuous paths which is of finite $\nu$-Hölder norm on any interval $[s, t]$. In particular, $x$ is a realization of a stochastic process $X_{t}(\omega)$ with stationary increments, such that $x$ can be lifted into a realized component $\mathbf{x}=(x, \mathbb{X})$ of a stochastic process $\left(x .(\omega), \mathbb{X}_{.,},(\omega)\right)$ with stationary increments, and the estimate

$$
\begin{equation*}
E\left(\left\|x_{s, t}\right\|^{p}+\left\|\mathbb{X}_{s, t}\right\|^{q}\right) \leq C_{T, \nu}|t-s|^{\mid \nu \nu}, \forall s, t \in[0, T] \tag{1.8}
\end{equation*}
$$

holds for any $[0, T]$, with $p \nu \geq 1, q=\frac{p}{2}$ and some constant $C_{T, \nu}$.

Let us comment on the assumptions. As presented in Remark 3.1, assumption $\left(\mathbf{H}_{X}\right)$ is satisfied if $X$ is a fractional Brownian motion $B^{H}$ [32] with Hurst exponent $H \in\left(\frac{1}{3}, 1\right)$, i.e. a family of centered Gaussian processes $B^{H}=\left\{B_{t}^{H}\right\}_{t \in \mathbb{R}}$ with continuous sample paths and

$$
E\left\|B_{t}^{H}-B_{s}^{H}\right\|=|t-s|^{2 H}, \forall t, s \in \mathbb{R}
$$

Meanwhile, the local Lipchitz continuity, condition (1.6) and the one-sided Lipschitz continuity

$$
\exists C>0:\langle y, f(y)\rangle \leq C\left(1+\|y\|^{2}\right), \quad \forall y \in \mathbb{R}^{d}
$$

are require for $f$ in order to prove the existence and uniqueness of the solution of (1.2), as well as the continuity of the solution semiflow and the generation of a continuous random dynamical system, see e.g. [35, Theorem 4.3] and [2]. In our situation, condition (1.5) is stronger than the one-sided Lipschitz continuity, and in fact is equivalent to the classical dissipativity, as shown in the following lemma.

Lemma 1.1 Condition (1.5) is equivalent to the following condition: there exist constants $d_{1} \geq$ $0, d_{2}>0$ such that

$$
\begin{equation*}
\langle y, f(y)\rangle \leq d_{1}-d_{2}\|y\|^{2}, \quad \forall y \in \mathbb{R}^{d} ; \tag{1.9}
\end{equation*}
$$

Proof: Assume (1.5) is satisfied, then Cauchy inequality yields

$$
\langle y, f(y)\rangle \leq \frac{D_{1}^{2}}{2 D_{2}}-\frac{D_{2}}{2}\|y\|^{2}-\frac{1}{2}\left(\sqrt{D_{2}}\|y\|-\frac{D_{1}}{\sqrt{D_{2}}}\right)^{2} \leq \frac{D_{1}^{2}}{2 D_{2}}-\frac{D_{2}}{2}\|y\|^{2},
$$

which proves (1.9) by choosing $d_{1}:=\frac{D_{1}^{2}}{2 D_{2}}$ and $d_{2}:=\frac{D_{2}}{2}$. For the other direction, one can easily show that

$$
\langle y, f(y)\rangle \leq\|y\|\left(\sup _{\|y\| \leq 1}\|f(y)\|+d_{1}+d_{2}-d_{2}\|y\|\right), \forall y \in \mathbb{R}^{d} .
$$

Indeed, if $\|y\| \leq 1$, then

$$
\langle y, f(y)\rangle \leq\|y\| \sup _{\|y\| \leq 1}\|f(y)\|+d_{2}\|y\|(1-\|y\|) \leq\|y\|\left(\sup _{\|y\| \leq 1}\|f(y)\|+d_{1}+d_{2}-d_{2}\|y\|\right) .
$$

On the other hand, if $\|y\| \geq 1$ then by (1.9)

$$
\langle y, f(y)\rangle \leq d_{1}-d_{2}\|y\|^{2} \leq d_{1}\|y\|-d_{2}\|y\|^{2} \leq\|y\|\left(\sup _{\|y\| \leq 1}\|f(y)\|+d_{1}+d_{2}-d_{2}\|y\|\right) .
$$

Hence (1.5) is followed by choosing $D_{1}:=\sup _{\|y\| \leq 1}\|f(y)\|+d_{1}+d_{2}$ and $D_{2}:=d_{2}$.
Due to Lemma 1.1, the deterministic system (1.4) is dissipative and admits a global attractor. In addition, the addition technical condition (1.6) is equivalent to the following: for $y \in \mathbb{R}^{d}$ and $y \neq 0$, $f(y)$ is decomposed in the unique form

$$
\begin{equation*}
f(y)=\frac{\langle f(y), y\rangle}{\|y\|^{2}} y+\pi_{y}^{\perp}(f(y)), \text { where } \pi_{y}^{\perp}=1-\pi_{y} \text { and }\left\|\pi_{y}^{\perp}(f(y))\right\| \leq C_{f}(1+\|y\|) . \tag{1.10}
\end{equation*}
$$

Condition (1.6) is automatically satisfied if $f$ is globally Lipschitz continuous, i.e.

$$
\begin{equation*}
\left\|f\left(y_{1}\right)-f\left(y_{2}\right)\right\| \leq L_{f}\left\|y_{1}-y_{2}\right\|, \quad \forall y_{1}, y_{2} \in \mathbb{R}^{d} \tag{1.11}
\end{equation*}
$$

or if $f$ is simply of linear growth, i.e. $\|f(y)\| \leq L_{f}(1+\|y\|)$. Thus the assumption $\left(\mathbf{H}_{f}\right)$ is weaker than the one in [19]. Nontrivial examples are presented in the following examples.

Example 1.2 Consider the vector field $f(y)=\chi y-\|y\|^{2} y$ for all $y \in \mathbb{R}^{d}$, where $\chi>0$ is a constant. Then it follows from Cauchy inequality that

$$
\langle y, f(y)\rangle=\|y\|\left(\chi-\|y\|^{3}\right) \leq\|y\|(\chi+2-3\|y\|) .
$$

On the other hand, $\pi_{y}^{\perp}(f(y))=0$ whenever $y \neq 0$. Hence (1.5) and (1.6) are satisfied.
By similar computations, one can easily check that the Poincaré-Andronov-Hopf vector field [22, Example 7.26, p. 208]

$$
f(y)=\binom{b y_{2}+y_{1}\left(a-y_{1}^{2}-y_{2}^{2}\right)}{-b y_{1}+y_{2}\left(a-y_{1}^{2}-y_{2}^{2}\right)}, \forall y=\left(y_{1}, y_{2}\right)^{\mathrm{T}} \in \mathbb{R}^{2},
$$

for constants $a, b>0$, also satisfies conditions (1.5) and (1.6). The function $a-y_{1}^{2}-y_{2}^{2}$ can also be generalized to $F(a,\|y\|)$ for a function $F$ that makes $f$ dissipative in the strong sense (see [22, Example 11.13, p.345]).

In addition, (1.5) ensures that there exists a global attractor $\mathcal{A}$ for the deterministic system (1.4) satisfying: for any solution $\mu_{t}$ starting at point $\mu_{0} \in \mathcal{A}$, we have

$$
\begin{align*}
& \left\|\mu_{t}\right\| \leq \underbrace{\max \{\|\mu\|: \mu \in \mathcal{A}\}}_{=:|\mathcal{A}|} \\
& \left\|\mu_{s, t}\right\| \leq \int_{s}^{t} \underbrace{\max \left\{\left\|f\left(p_{1}\right)\right\|: p_{1} \in \mathcal{A}\right\}}_{=:\|f\|_{\infty, \mathcal{A}}} d u=\|f\|_{\infty, \mathcal{A}}(t-s), \quad \forall 0 \leq s<t \tag{1.12}
\end{align*}
$$

thus $\mu \in C^{1-\mathrm{var}}$.
One approach to show stochastic perturbation is to prove that a global random attractor does exist and is upper semi-continuous w.r.t the intensity of the stochastic noise (see e.g. [3], [4], [23], [38]). To do that, we need to impose an additional property of uniform attraction for the global attractor $\mathcal{A}$ as follows.
$\left(\mathbf{H}_{\mathcal{A}}\right)$ There exists a duration $r>0$ and constants $D_{3}>0$ of the deterministic system (1.4) such that, for any starting point $y_{0} \notin \mathcal{A}$, there exists a point $\mu_{0}=\mu_{0}\left(y_{0}\right) \in \mathcal{A}$ satisfying

$$
\begin{equation*}
\left\|\mu_{r}\left(y_{0}\right)-\mu_{r}\left(\mu_{0}\right)\right\| \leq e^{-D_{3}}\left\|y_{0}-\mu_{0}\right\| . \tag{1.13}
\end{equation*}
$$

For instance, asumption $\left(\mathbf{H}_{\mathcal{A}}\right)$ is satisfied when $f$ is strictly dissipative, i.e. $D_{1}=0$ in (1.5), by choosing $D_{3}=D_{2}$ and $r=1$. Another example is any planar system satisfying $\left(\mathbf{H}_{f}\right)$ which admits a periodic orbit that also acts as the boundary of the global attractor, see e.g. [22, Chapter 11]. Condition (1.13) is then equivalent to the exponential stability of the fixed point of the Poincaré map.

Our main results (Theorem 3.3, Theorem 3.4, Theorem 3.7) show that, under the assumptions $\left(\mathbf{H}_{f}\right),\left(\mathbf{H}_{g}\right),\left(\mathbf{H}_{X}\right)$, there exists a random pullback attractor $\mathcal{A}(\omega)$ such that $|\mathcal{A}(\cdot)| \in \mathcal{L}^{\rho}$ for any $\rho \geq 1$. In addition, if condition $\left(\mathbf{H}_{f}\right)$ is replaced by conditions on the relative dissipativity (will be specified later in Theorem 3.4), the global Lipschitz continuity (1.11) and $\left(\mathbf{H}_{\mathcal{A}}\right)$, then the random attractor is upper semi-continuous with respect to the noise intensity in the sense that $\mathcal{A}(\omega) \rightarrow \mathcal{A}$ (w.r.t. the Hausdorff semi-distance) as $C_{g} \rightarrow 0$, both in the almost sure and in $\mathcal{L}^{\rho}$ senses. Moreover, if $f$ is strictly dissipative then $\mathcal{A}(\omega)$ is a singleton provided that $C_{g}$ is sufficiently small.

Our idea of the proof uses a well-known Doss-Sussmann technique [37], which was developed in [28], [27], [35], [10] for stochastic systems, i.e. using the transformation $y_{t}=\phi_{t}\left(\mathbf{x}, z_{t}\right)$ generated from the pure rough differential equation $d \phi_{t}=g\left(\phi_{t}\right) d x_{t}$. The solution of the transformed system

$$
\begin{equation*}
\dot{z}_{t}=\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1} f\left(\phi_{t}\left(\mathbf{x}, z_{t}\right)\right) \tag{1.14}
\end{equation*}
$$

can then be estimated on each interval of a greedy sequence of stopping times generated from the rough path $\mathbf{x}$ [5]. The case $\nu>\frac{1}{3}$ is therefore just for the aim of simple presentation. Our results and methods in this paper still hold for smaller $\nu$, provided that almost all realizations of the stochastic noise are truly rough so that the Gubinelli derivative can be uniquely defined (see details in Subsection 2.2). Plus, we would need additional information in the signatures of rough paths to define rough integrals for controlled rough paths.

Finally, we emphasize here that there is of course a similar way to achieve the results for solutions of (1.2) understood in the sense of Lyons-Davie, by using [5]. However, our usage of rough integrals in the Gubinelli sense is not just a matter of taste, but because it provides short and self-contained proofs, and can be generalized for studying infinite dimensional systems with rough noises, as partly seen in [7] for stochastic systems with time delays.

## 2 Preliminaries

### 2.1 Rough paths

Let us introduce the concept of rough paths, following [30] and [13]. Given any compact time interval $I=[\min I, \max I] \subset \mathbb{R}$, we write $|I|:=\max I-\min I$ and $I^{2}:=I \times I$. For any finite dimensional vector space $W$, denote by $C(I, W)$ the space of all continuous paths $y: I \rightarrow W$ equipped with the sup norm $\|\cdot\|_{\infty, I}$ given by $\|y\|_{\infty, I}=\sup _{t \in I}\left\|y_{t}\right\|$, where $\|\cdot\|$ is the norm in $W$. We write $y_{s, t}:=y_{t}-y_{s}$. For $p \geq 1$, denote by $C^{p-\operatorname{var}}(I, W) \subset C(I, W)$ the space of all continuous paths $y: I \rightarrow W$ of finite $p$-variation $\|y\|_{p-\mathrm{var}, I}:=\left(\sup _{\Pi(I)} \sum_{i=1}^{n}\left\|y_{t_{i}, t_{i+1}}\right\|^{p}\right)^{1 / p}<\infty$, where the supremum is taken over the whole class of finite partition of $I$. It is well known [14] that $\|y\|_{p-\mathrm{var}, I}^{p}$ is a control, i.e. it satisfies

$$
\begin{equation*}
\|y\|_{p-\operatorname{var},[s, s]}^{p}=0, \quad\|y\|_{p-\mathrm{var},[s, u]}^{p}+\|y\|_{p-\operatorname{var},[u, t]}^{p} \leq\|y\|_{p-\operatorname{var},[s, t]}^{p}, \quad \forall s \leq u \leq t . \tag{2.1}
\end{equation*}
$$

Then $C^{p-\operatorname{var}}(I, W)$ with the equipped $p-\operatorname{var}$ norm $\|y\|_{p-\operatorname{var}, I}:=\left\|y_{\min I}\right\|+\|y\|_{p-\mathrm{var}, \mathrm{I}}$ is a nonseparable Banach space [14, Theorem 5.25, p. 92]. Also for each $0<\alpha<1$, we denote by $C^{\alpha}(I, W)$ the space of Hölder continuous functions with exponent $\alpha$ on $I$ equipped with the norm

$$
\begin{equation*}
\|y\|_{\alpha, I}:=\left\|y_{\min I}\right\|+\|y\|_{\alpha, I}, \quad \text { where } \quad\|y\|_{\alpha, I}:=\sup _{s, t \in I, s<t} \frac{\left\|y_{s, t}\right\|}{(t-s)^{\alpha}}<\infty . \tag{2.2}
\end{equation*}
$$

For $\alpha \in\left(\frac{1}{3}, \frac{1}{2}\right)$, a couple $\mathbf{x}=(x, \mathbb{X}) \in \mathbb{R}^{m} \oplus\left(\mathbb{R}^{m} \otimes \mathbb{R}^{m}\right)$, where $x \in C^{\alpha}\left(I, \mathbb{R}^{m}\right)$ and

$$
\mathbb{X} \in C^{2 \alpha}\left(I^{2}, \mathbb{R}^{m} \otimes \mathbb{R}^{m}\right):=\left\{\mathbb{X} \in C\left(I^{2}, \mathbb{R}^{m} \otimes \mathbb{R}^{m}\right): \sup _{s, t \in I, s<t} \frac{\left\|\mathbb{X}_{s, t}\right\|}{|t-s|^{2 \alpha}}<\infty\right\}
$$

is called a rough path if it satisfies Chen's relation

$$
\begin{equation*}
\mathbb{X}_{s, t}-\mathbb{X}_{s, u}-\mathbb{X}_{u, t}=x_{s, u} \otimes x_{u, t}, \quad \forall \min I \leq s \leq u \leq t \leq \max I \tag{2.3}
\end{equation*}
$$

$\mathbb{X}$ is called a Lévy area for $x$ and is viewed as postulating the value of the quantity $\int_{s}^{t} x_{s, r} \otimes d x_{r}:=\mathbb{X}_{s, t}$ where the right hand side is taken as a definition for the left hand side. Denote by $\mathscr{C}^{\alpha}\left(I, \mathbb{R}^{m} \oplus\right.$ $\left.\left(\mathbb{R}^{m} \otimes \mathbb{R}^{m}\right)\right) \subset C^{\alpha}\left(I, \mathbb{R}^{m}\right) \oplus C^{2 \alpha}\left(I^{2}, \mathbb{R}^{m} \otimes \mathbb{R}^{m}\right)$ the set of all rough paths $\mathbf{x}$ on $I$ (or in short $\mathscr{C}^{\alpha}(I)$ ), then $\mathscr{C}^{\alpha}(I)$ is a closed set (but not a linear space), equipped with the rough path semi-norm

$$
\begin{equation*}
\|\mathbf{x}\|_{\alpha, I}:=\|x\|_{\alpha, I}+\|\mathbb{X}\|_{2 \alpha, I^{2}}^{\frac{1}{2}}, \quad \text { where } \quad\|\mathbb{X}\|_{2 \alpha, I^{2}}:=\sup _{s, t \in I ; s<t} \frac{\left\|\mathbb{X}_{s, t}\right\|}{|t-s|^{2 \alpha}}<\infty \tag{2.4}
\end{equation*}
$$

Throughout this paper, we will fix parameters $\frac{1}{3}<\alpha<\nu<\frac{1}{2}$ and $p=\frac{1}{\alpha}$ so that $C^{\alpha}(I, W) \subset$ $C^{p-\mathrm{var}}(I, W)$. We also set $q=\frac{p}{2}$ and consider the $p-$ var semi-norm

$$
\begin{align*}
\|\mathbf{x}\|_{p-\mathrm{var}, I} & :=\left(\|x\|_{p-\mathrm{var}, I}^{p}+\|\mathbb{X}\|_{q-\mathrm{var}, I^{2}}^{q}\right)^{\frac{1}{p}}, \\
\|\mathbb{X}\|_{q-\mathrm{var}, I^{2}} & :=\left(\sup _{\Pi(I)} \sum_{i=1}^{n}\left\|\mathbb{X}_{t_{i}, t_{i+1}}\right\|^{q}\right)^{1 / q}, \tag{2.5}
\end{align*}
$$

where the supremum is taken over the whole class of finite partitions $\Pi(I)$ of $I$. Sometimes, we write $\mathscr{C}^{\alpha}(I)$ for abbreviation to neglect the value space for simplicity of presentation.

### 2.2 Rough integrals

Following [17], a rough integral can be defined for a continuous path $y \in C^{\alpha}(I, W)$ which is controlled by $x \in C^{\alpha}\left(I, \mathbb{R}^{m}\right)$ in the sense that, there exists a couple $\left(y^{\prime}, R^{y}\right)$ with $y^{\prime} \in C^{\alpha}\left(I, \mathcal{L}\left(\mathbb{R}^{m}, W\right)\right), R^{y} \in$ $C^{2 \alpha}\left(I^{2}, W\right)$ such that

$$
\begin{equation*}
y_{s, t}=y_{s}^{\prime} x_{s, t}+R_{s, t}^{y}, \quad \forall \min I \leq s \leq t \leq \max I . \tag{2.6}
\end{equation*}
$$

$y^{\prime}$ is called the Gubinelli derivative of $y$, which is uniquely defined as long as $x$ is truly rough [13, Definition 6.3 \& Proposition 6.4], namely there exists a dense set of instants $s$ of $I$ such that $x$ is "rough at time $s$ ", i.e.

$$
\forall h^{*} \in\left(\mathbb{R}^{m}\right)^{*} \backslash\{0\}: \quad \limsup _{t \downarrow s} \frac{\left|\left\langle h^{*}, x_{s, t}\right\rangle\right|}{|t-s|^{2 \alpha}}=\infty
$$

For instance, almost all trajectories of a fractional Brownian motion $B^{H}$ with $H>\frac{1}{3}$ is truly rough [13, Section 6].

Denote by $\mathscr{D}_{x}^{2 \alpha}(I)$ the space of all the couples $\left(y, y^{\prime}\right)$ controlled by $x$, then $\mathscr{D}_{x}^{2 \alpha}(I)$ is a Banach space equipped with the norm

$$
\begin{aligned}
\left\|\left(y, y^{\prime}\right)\right\|_{x, 2 \alpha, I} & :=\left\|y_{\min I}\right\|+\left\|y_{\min I}^{\prime}\right\|+\left\|\left(y, y^{\prime}\right)\right\|_{x, 2 \alpha, I}, \\
\left\|\left(y, y^{\prime}\right)\right\|_{x, 2 \alpha, I} & :\left\|y^{\prime}\right\|_{\alpha, I}+\left\|R^{y}\right\|_{2 \alpha, I^{2}}
\end{aligned}
$$

Then for a fixed rough path $\mathbf{x}=(x, \mathbb{X})$ and any controlled rough path $\left(y, y^{\prime}\right) \in \mathscr{D}_{x}^{2 \alpha}(I)$, the integral $\int_{s}^{t} y_{u} d x_{u}$ can be defined as the limit of the Darboux sum

$$
\int_{s}^{t} y_{u} d x_{u}:=\lim _{|\Pi| \rightarrow 0} \sum_{[u, v] \in \Pi}\left(y_{u} \otimes x_{u, v}+y_{u}^{\prime} \mathbb{X}_{u, v}\right)
$$

where the limit is taken on all finite partitions $\Pi$ of $I$ with $|\Pi|:=\max _{[u, v] \in \Pi}|v-u|$. Moreover, there exists a constant $C_{\alpha}=C_{\alpha,|I|}>1$, such that

$$
\begin{align*}
& \left\|\int_{s}^{t} y_{u} d x_{u}-y_{s} \otimes x_{s, t}-y_{s}^{\prime} \mathbb{X}_{s, t}\right\|  \tag{2.7}\\
\leq & C_{\alpha}|t-s|^{3 \alpha}\left(\|x\|_{\alpha,[s, t]}\left\|R^{y}\right\|_{2 \alpha,[s, t]^{2}}+\left\|y^{\prime}\right\|\left\|_{\alpha,[s, t]}\right\| \mathbb{X} \|_{2 \alpha,[s, t]^{2}}\right) .
\end{align*}
$$

In our paper, we often use the $p$-variation norm

$$
\begin{aligned}
\left\|\left(y, y^{\prime}\right)\right\|_{x, p, I} & :=\left\|y_{\min I}\right\|+\left\|y_{\min I}^{\prime}\right\|+\left\|\left(y, y^{\prime}\right)\right\|_{x, p, I}, \\
\left\|\left(y, y^{\prime}\right)\right\|_{x, p, I} & :=\left\|y^{\prime}\right\|_{p-\mathrm{var}, I}+\left\|R^{y}\right\|_{q-\mathrm{var}, I^{2}},
\end{aligned}
$$

and a similar version to (2.7) under $p$-variation semi-norm as follows

$$
\begin{align*}
& \left\|\int_{s}^{t} y_{u} d x_{u}-y_{s} \otimes x_{s, t}-y_{s}^{\prime} \mathbb{X}_{s, t}\right\|  \tag{2.8}\\
\leq & C_{p}\left(\|x\|_{p-\operatorname{var},[s, t]}\left\|R^{y}\right\|_{q-\operatorname{var},[s, t]^{2}}+\left\|y^{\prime}\right\|_{p-\mathrm{var},[s, t]}\|\mathbb{X}\|_{q-\operatorname{var},[s, t]^{2}}\right),
\end{align*}
$$

with constant $C_{p}>1$ independent of $\mathbf{x}$ and $\left(y, y^{\prime}\right)$.

### 2.3 Rough differential equations

The existence and uniqueness theorem for system (1.2) is first proved in [35], where the solution is understood in the sense of Friz-Victoir [14]. By using rough integrals, we would like to interpret the rough differential equation (1.2) by writing it in the integral form

$$
\begin{equation*}
y_{t}=y_{\min I}+\int_{\min I}^{t} f\left(y_{s}\right) d s+\int_{\min I}^{t} g\left(y_{s}\right) d x_{s}, \quad \forall t \in I, \tag{2.9}
\end{equation*}
$$

for any interval $I$ and an initial value $y_{\min I} \in \mathbb{R}^{d}$, and we search for a solution in the Gubinelli sense $(y, y \prime) \in \mathscr{D}_{x}^{2 \alpha}\left(I, \mathbb{R}^{d}\right)$. This is possible because for $g: \mathbb{R}^{d} \rightarrow \mathcal{L}\left(\mathbb{R}^{m}, \mathbb{R}^{d}\right)$ satisfying $\left(\mathbf{H}_{2}\right)$, it is easy to prove (see e.g. [17]) that

$$
\begin{aligned}
\left(y, y^{\prime}\right) \in \mathscr{D}_{x}^{2 \alpha}\left(I, \mathbb{R}^{d}\right) \Rightarrow & \left(g(y),[g(y)]^{\prime}\right) \in \mathscr{D}_{x}^{2 \alpha}\left(I, \mathcal{L}\left(\mathbb{R}^{m}, \mathbb{R}^{d}\right)\right) \\
& \text { with } \quad[g(y)]_{s}^{\prime}=D g\left(y_{s}\right) y_{s}^{\prime} \in \mathcal{L}\left(\mathbb{R}^{m}, \mathcal{L}\left(\mathbb{R}^{m}, \mathbb{R}^{d}\right)\right) ;
\end{aligned}
$$

thus the second integral in (2.9) is well defined.
The existence and uniqueness theorem and the norm estimates for solution of (2.9) are recently proved in [10] under the Lipschitz continuity assumption (1.11), by using the Doss-Sussmann technique [37] and the so-called greedy sequence of stopping times in [5]. Namely, for any fixed $\gamma \in(0,1)$ the sequence of greedy times $\left\{\tau_{i}(\gamma, \mathbf{x}, I)\right\}_{i \in \mathbb{N}}$ is defined by

$$
\begin{equation*}
\tau_{0}=\min I, \quad \tau_{i+1}:=\inf \left\{t>\tau_{i}:\|\mathbf{x}\|_{p-\operatorname{var},\left[\tau_{i}, t\right]}=\gamma\right\} \wedge \max I . \tag{2.10}
\end{equation*}
$$

Define $N(\gamma, \mathbf{x}, I):=\sup \left\{i \in \mathbb{N}: \tau_{i} \leq \max I\right\}$, then it is easy to show a rough estimate

$$
\begin{equation*}
N(\gamma, \mathbf{x}, I) \leq 1+\gamma^{-p}\|\mathbf{x}\|_{p-\operatorname{var}, I}^{p} . \tag{2.11}
\end{equation*}
$$

Other studies on continuity and properties of stopping times can also be founded in [6, Section 2.2] or [11, Section 4].

Note that from [10, Theorem 3.4], the solution $\phi .\left(\mathbf{x}, \phi_{a}\right)$ of the pure rough differential equation

$$
\begin{equation*}
d \phi_{u}=g\left(\phi_{u}\right) d x_{u}, \quad u \in[a, b], \phi_{a} \in \mathbb{R}^{d} \tag{2.12}
\end{equation*}
$$

is $C^{1}$ w.r.t. $\phi_{a}$, and $\frac{\partial \phi}{\partial \phi_{a}}\left(\cdot, \mathbf{x}, \phi_{a}\right)$ is the solution of the linearized system

$$
\begin{equation*}
d \xi_{u}=D g\left(\phi_{u}\left(\mathbf{x}, \phi_{s}\right)\right) \xi_{u} d x_{u}, \quad u \in[a, b], \xi_{a}=I d, \tag{2.13}
\end{equation*}
$$

where $I d \in \mathbb{R}^{d \times d}$ denotes the identity matrix.
We introduce the semi-norm $\left\|\kappa, R^{\kappa}\right\|_{p-\mathrm{var},[s, t]}:=\|\kappa\|_{p-\mathrm{var},[s, t]}+\left\|R^{\kappa}\right\|_{q-\mathrm{var},[s, t]]^{2}}$. The following result shows solution norm estimates for equation (2.12).

Proposition 2.1 Assume that $\phi_{t}, \bar{\phi}_{t}$ are the solutions of (2.12). Then for any interval $[a, b]$ such that $16 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]} \leq 1$, the following estimates hold

$$
\begin{align*}
\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]} & \leq 8 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}  \tag{2.14}\\
\left\|\bar{\phi}-\phi, R^{\bar{\phi}-\phi}\right\|_{p-\mathrm{var},[a, b]} & \leq 16 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}\left\|\bar{\phi}_{a}-\phi_{a}\right\| ;  \tag{2.15}\\
\|\bar{\phi}-\phi\|_{\infty,[a, b]} & \leq 2\left\|\bar{\phi}_{a}-\phi_{a}\right\| \tag{2.16}
\end{align*}
$$

Proof: Because

$$
\begin{aligned}
g\left(\phi_{t}\right)-g\left(\phi_{s}\right)= & \int_{0}^{1} D g\left(\phi_{s}+\eta \phi_{s, t}\right) \phi_{s, t} d \eta \\
= & D_{g}\left(\phi_{s}\right) \phi_{s}^{\prime} \otimes x_{s, t}+\int_{0}^{1} D g\left(\phi_{s}+\eta \phi_{s, t}\right) R_{s, t}^{\phi} d \eta \\
& +\int_{0}^{1}\left[D g\left(\phi_{s}+\eta \phi_{s, t}\right)-D g\left(\phi_{s}\right)\right] \phi_{s, t}^{\prime} \otimes x_{s, t} d \eta
\end{aligned}
$$

it follows that $[g(\phi)]_{s}^{\prime}=D g\left(\phi_{s}\right) g\left(\phi_{s}\right)$, where we use (1.7) to estimate

$$
\begin{aligned}
\left\|R_{s, t}^{g(\phi)}\right\| \leq & \int_{0}^{1}\left\|D g\left(\phi_{s}+\eta \phi_{s, t}\right)\right\|\left\|R_{s, t}^{\phi}\right\| d \eta \\
& +\int_{0}^{1}\left\|D g\left(\phi_{s}+\eta \phi_{s, t}\right)-D g\left(\phi_{s}\right)\right\|\left\|g\left(\phi_{s}\right)\right\|\left\|x_{s, t}\right\| d \eta \\
\leq & C_{g}\left\|R_{s, t}^{\phi}\right\|+\frac{1}{2} C_{g}^{2}\left\|\phi_{s, t}\right\|\left\|x_{s, t}\right\|
\end{aligned}
$$

This together with Hölder inequality yields

$$
\begin{aligned}
\left\|[g(\phi)]^{\prime}\right\|_{p-\mathrm{var},[a, b]} & \leq 2 C_{g}^{2}\|\phi\|_{p-\mathrm{var},[a, b]}, \quad\left\|[g(\phi)]^{\prime}\right\|_{\infty,[a, b]} \leq C_{g}^{2} \\
\left\|R^{g(\phi)}\right\|_{q-\mathrm{var},[a, b]^{2}} & \leq C_{g}\left\|R^{\phi}\right\|_{q-\mathrm{var},[a, b]^{2}}+\frac{1}{2} C_{g}^{2}\|x\|_{p-\mathrm{var},[a, b]}\|\phi\|_{p-\mathrm{var},[a, b]}
\end{aligned}
$$

Assumption $16 C_{p} C_{g}\|\mathrm{x}\|_{p-\mathrm{var},[a, b]} \leq 1$ follows that

$$
4 C_{g}^{2}\|\mathbf{x}\|_{p-\operatorname{var},[a, b]}^{2} \leq C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}<1
$$

By applying (2.5) and (2.8), we obtain for any $a \leq s<t \leq b$

$$
\begin{aligned}
& \left\|\phi_{s, t}\right\| \\
\leq & \left\|\int_{s}^{t} g\left(\phi_{u}\right) d x_{u}\right\| \\
\leq & C_{g}\|x\|_{p-\mathrm{var},[s, t]}+C_{g}^{2}\|\mathbb{X}\|_{q-\mathrm{var},[s, t]^{2}} \\
& +C_{p}\left\{\|x\|_{p-\mathrm{var},[s, t]}\| \| R^{g(\phi)}\left\|_{q-\mathrm{var},[s, t]^{2}}+\right\| \mathbb{X}\left\|_{q-\mathrm{var},[s, t]^{2}}\right\|[g(\phi)]^{\prime} \|_{p-\mathrm{var},[a, b]}\right\} \\
\leq & 2\left\{C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]} \vee 4 C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}^{2}\right\}\left(1+C_{p}\left\|\phi, R^{\phi}\right\| \|_{p-\mathrm{var},[s, t]}\right) \\
\leq & 2 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}\left(1+\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]}\right)
\end{aligned}
$$

which, by the definition of $p$-variation seminorm and (2.1), derives

$$
\|\phi\|_{p-\operatorname{var},[a, b]} \leq 2 C_{p} C_{g}\left\{\sup _{\Pi[a, b]} \sum_{[s, t] \in \Pi([a, b])}\|\mathbf{x}\|_{p-\operatorname{var},[s, t]}^{p}\right\}^{\frac{1}{p}}\left(1+\left\|\phi, R^{\phi}\right\|_{p-\operatorname{var},[a, b]}\right)
$$

$$
\leq 2 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}\left(1+\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]}\right)
$$

The same estimate for $R^{\phi}$ is actually included in the above estimate, hence

$$
\begin{aligned}
\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]} & \leq 4 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}\left(1+\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]}\right) \\
& \leq 4 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}+\frac{1}{2}\left\|\phi, R^{\phi}\right\| \|_{p-\mathrm{var},[a, b]}
\end{aligned}
$$

which proves (2.14).
Next, for any two solutions $\phi_{t}\left(\mathbf{x}, \phi_{a}\right)$ and $\bar{\phi}_{t}\left(\mathbf{x}, \bar{\phi}_{a}\right)$ of (2.12), consider their difference $\bar{\phi}_{t}-\phi_{t}$, which satisfies the rough differential equation $d\left(\bar{\phi}_{t}-\phi_{t}\right)=\left[g\left(\bar{\phi}_{t}\right)-g\left(\phi_{t}\right)\right] d x_{t}$. Because

$$
\begin{aligned}
& g\left(\bar{\phi}_{t}\right)-g\left(\phi_{t}\right)-g\left(\bar{\phi}_{s}\right)+g\left(\phi_{s}\right) \\
= & {\left[D g\left(\bar{\phi}_{s}\right) g\left(\bar{\phi}_{s}\right)-D g\left(\phi_{s}\right) g\left(\phi_{s}\right)\right] \otimes x_{s, t} } \\
& +\int_{0}^{1}\left\{D g\left(\bar{\phi}_{s}+\eta \bar{\phi}_{s, t}\right) R_{s, t}^{\bar{\phi}-\phi}+\left[D g\left(\bar{\phi}_{s}+\eta \bar{\phi}_{s, t}\right)-D g\left(\phi_{s}+\eta \phi_{s, t}\right)\right] R_{s, t}^{\phi}\right\} d \eta \\
& +\int_{0}^{1}\left[D g\left(\bar{\phi}_{s}+\eta \bar{\phi}_{s, t}\right)-D g\left(\bar{\phi}_{s}\right)\right]\left[g\left(\bar{\phi}_{s}\right)-g\left(\phi_{s}\right)\right] \otimes x_{s, t} d \eta \\
& +\left(\int_{0}^{1} \int_{0}^{1} D^{2} g\left(\bar{\phi}_{s}+\mu \eta \bar{\phi}_{s, t}\right) \eta\left(\bar{\phi}_{s, t}-\phi_{s, t}\right) d \mu d \eta\right) g\left(\phi_{s}\right) \otimes x_{s, t} \\
& +\left(\int_{0}^{1} \int_{0}^{1}\left[D^{2} g\left(\bar{\phi}_{s}+\mu \eta \bar{\phi}_{s, t}\right)-D^{2} g\left(\phi_{s}+\mu \eta \phi_{s, t}\right) \eta \phi_{s, t}\right] d \mu d \eta\right) g\left(\phi_{s}\right) \otimes x_{s, t} .
\end{aligned}
$$

it follows that $[g(\bar{\phi})-g(\phi)]_{s}^{\prime}=D g\left(\bar{\phi}_{s}\right) g\left(\bar{\phi}_{s}\right)-D g\left(\phi_{s}\right) g\left(\phi_{s}\right)$ which has the form $Q\left(\bar{\phi}_{s}\right)-Q\left(\phi_{s}\right)$. Notice that $\left\|Q\left(\bar{\phi}_{s}\right)-Q\left(\phi_{s}\right)\right\| \leq 2 C_{g}^{2}\left\|\bar{\phi}_{s}-\phi_{s}\right\|$ and

$$
\begin{aligned}
\|Q(\bar{\phi})-Q(\phi)\|_{p-\operatorname{var},[s, t]} & \leq C_{Q}\left(\|\bar{\phi}-\phi\|_{p-\operatorname{var},[s, t]}+\|\bar{\phi}-\phi\|_{\infty,[s, t]}\| \| \|_{p-\operatorname{var},[s, t]}\right) \\
& \leq 2 C_{g}^{2}\left(\|\bar{\phi}-\phi\|_{p-\operatorname{var},[s, t]}+\|\bar{\phi}-\phi\|_{\infty,[s, t]}\|\phi\|_{p-\operatorname{var},[s, t]}\right) .
\end{aligned}
$$

On the other hand

$$
\begin{array}{r}
\left\|R^{g(\bar{\phi})-g(\phi)}\right\|_{q-\operatorname{var},[s, t]^{2}} \leq \\
C_{g}\| \| R^{\bar{\phi}-\phi}\left\|_{q-\operatorname{var},[s, t]^{2}}+C_{g}\right\| \bar{\phi}-\phi\left\|_{\infty,[s, t]}\right\|\left\|R^{\phi}\right\| \|_{q-\operatorname{var},[s, t]^{2}} \\
+\frac{1}{2} C_{g}^{2}\|x\|_{p-\operatorname{var},[s, t]}\left[\|\bar{\phi}-\phi\|_{p-\operatorname{var},[s, t]}\right. \\
\left.\quad+\|\bar{\phi}-\phi\|_{\infty}\left(\|\bar{\phi}\|_{p-\operatorname{var},[s, t]}+\|\phi\|_{p-\operatorname{var},[s, t]}\right)\right] .
\end{array}
$$

This leads to the estimate

$$
\begin{align*}
\left\|\bar{\phi}_{s, t}-\phi_{s, t}\right\| \leq & \left\|\int_{s}^{t}\left[g\left(\bar{\phi}_{u}\right)-g\left(\phi_{u}\right)\right] d x_{u}\right\| \\
\leq & C_{g}\left\|\bar{\phi}_{s}-\phi_{s}\right\|\|x\|_{p-\operatorname{var},[s, t]}+2 C_{g}^{2}\left\|\bar{\phi}_{s}-\phi_{s}\right\|\|\mathbb{X}\|_{q-\operatorname{var},[s, t]^{2}} \\
& +C_{p}\left\{\|x\|_{p-\operatorname{var},[s, t]}\left\|R^{g(\bar{\phi})-g(\phi)}\right\| \|_{q-\mathrm{var},[s, t]^{2}}\right. \\
& \left.\quad+\|\mathbb{X}\|_{q-\operatorname{var},[s, t]^{2}}\left\|[g(\bar{\phi})-g(\phi)]^{\prime}\right\| \|_{p-\mathrm{var},[s, t]}\right\}, \tag{2.17}
\end{align*}
$$

which yields

$$
\|\bar{\phi}-\phi\|_{p-\mathrm{var},[a, b]} \leq 2 C_{p}\left\{C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]} \vee 4 C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}^{2}\right\}
$$

$$
\begin{align*}
& \times\left(1+\left\|\bar{\phi}, R^{\bar{\phi}}\right\|_{p-\operatorname{var},[a, b]}+\left\|\phi, R^{\phi}\right\|_{p-\operatorname{var},[a, b]}\right) \\
& \times\left(\left\|\bar{\phi}_{a}-\phi_{a}\right\|+\left\|\bar{\phi}-\phi, R^{\bar{\phi}-\phi}\right\|_{p-\mathrm{var},[a, b]}\right) . \tag{2.18}
\end{align*}
$$

The similar estimate for $\left\|\left\|R^{\bar{\phi}-\phi}\right\|_{q-\mathrm{var},[a, b]}\right.$ is already included in the estimate (2.17), hence

$$
\begin{aligned}
\left\|\bar{\phi}-\phi, R^{\bar{\phi}-\phi}\right\|_{p-\mathrm{var},[a, b]} \leq & 4 C_{p}\left\{C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]} \vee C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[a, b]}^{2}\right\} \\
& \times\left(1+\left\|\bar{\phi}, R^{\bar{\phi}}\right\|_{p-\mathrm{var},[a, b]}+\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[a, b]}\right) \\
& \times\left(\left\|\bar{\phi}_{a}-\phi_{a}\right\|+\left\|\bar{\phi}-\phi, R^{\bar{\phi}-\phi}\right\| \|_{p-\mathrm{var},[a, b]}\right),
\end{aligned}
$$

which, together with (2.14), leads to (2.15) and (2.16).
Since $\phi .\left(\mathbf{x}, \phi_{a}\right)$ is $C^{1}$ w.r.t. $\phi_{a}\left[10\right.$, Theorem 3.4], by dividing both sides of (2.15) by $\left\|\bar{\phi}_{a}-\phi_{a}\right\|$ and then letting $\bar{\phi}_{a}-\phi_{a}$ to zero, we obtain

$$
\begin{align*}
\left\|\frac{\partial \phi}{\partial \phi_{a}}\left(t, \mathbf{x}, \phi_{a}\right)-I d\right\| & \leq\left\|\frac{\partial \phi}{\partial \phi_{a}}\left(\cdot, \mathbf{x}, \phi_{a}\right), R^{\frac{\partial \phi}{\partial \phi_{a}}\left(\cdot, \mathbf{x}, \phi_{a}\right)}\right\|_{p-\mathrm{var},[a, b]}  \tag{2.19}\\
& \leq 16 C_{p} C_{g}\|\mathbf{x}\|_{p-\operatorname{var},[a, b]} .
\end{align*}
$$

Note that (2.14), (2.15) still hold for the backward equation

$$
\begin{equation*}
h_{b}=h_{t}+\int_{t}^{b} g\left(h_{u}\right) d x_{u}, \quad \forall t \in[a, b], \tag{2.20}
\end{equation*}
$$

thus (2.19) still holds if $\frac{\partial \phi}{\partial \phi_{s}}\left(t, \mathbf{x}, \phi_{s}\right)$ is replaced by $\left[\frac{\partial \phi}{\partial \phi_{s}}\left(t, \mathbf{x}, \phi_{s}\right)\right]^{-1}$, which is also the linearization of the solution of (2.20) (see e.g. [10, Corollary 3.5, Theorem 3.7]).

As shown in [35, Theorem 4.3], the local Lipschitz continuity, the one-sided Lipschitz continuity and (1.6) for $f$ are enough to prove the existence and uniqueness of solution of rough equation (1.2). Here we need to go one more step to prove the solution estimate of (1.2), under condition $\left(\mathbf{H}_{f}\right)$.

Theorem 2.2 Under the assumptions $\left(\boldsymbol{H}_{f}\right),\left(\boldsymbol{H}_{g}\right),\left(\boldsymbol{H}_{X}\right)$, there exists a solution of (1.2) on any interval $[0, T]$. Moreover, for any $\lambda>0$ small enough, there exist constants $\delta_{\lambda}, C_{\lambda}>0$ such that the following estimates hold

$$
\begin{equation*}
\left\|y_{t}\right\| \leq\left\|y_{0}\right\| e^{-\delta_{\lambda} t}+C_{\lambda} N\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x},[0, t]\right), \quad \forall t \in[0, T] . \tag{2.21}
\end{equation*}
$$

Proof: The idea is to prove the existence and uniqueness of the solution on each small interval between two consecutive stopping times, and then concatenate to obtain the conclusion on any interval. The Doss-Sussmann technique used in [35] and [10, Theorem 3.7] ensures that, by a transformation $y_{t}=\phi_{t}\left(\mathbf{x}, z_{t}\right)$ there is an one-one correspondence between a solution $y_{t}$ of (1.2) on a certain interval $[0, \tau]$ and a solution $z_{t}$ of the associated ordinary differential equation

$$
\begin{equation*}
\dot{z}_{t}=\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1} f\left(\phi_{t}\left(\mathbf{x}, z_{t}\right)\right), \quad t \in[0, \tau], z_{0}=y_{0} . \tag{2.22}
\end{equation*}
$$

Since $f$ is locally Lipschitz continuous, there exists a unique solution for (2.22) on some local interval $\tau_{\text {local }}$. To estimate the solution norm growth, assign $\gamma_{t}:=y_{t}-z_{t}$ and $\psi_{t}:=\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1}-I d$ for $t \in\left[0, \tau \wedge \tau_{\text {local }}\right]$, where $\tau>0$ is chosen such that $16 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[0, \tau]} \leq \lambda$ for some $\lambda \in(0,1)$ small
enough (which will be specified later). With such $\tau$, it then follows from Proposition 2.1 and (2.19) that

$$
\begin{equation*}
\left\|\gamma_{t}\right\|=\left\|\phi_{t}\left(\mathbf{x}, z_{t}\right)-z_{t}\right\| \leq \frac{\lambda}{2} \quad \text { and } \quad\left\|\psi_{t}\right\| \leq \lambda, \quad \forall t \in\left[0, \tau \wedge \tau_{\text {local }}\right] \tag{2.23}
\end{equation*}
$$

To estimate $\left\|z_{t}\right\|$, we rewrite (2.22) as

$$
\begin{equation*}
\dot{z}_{t}=\left(I d+\psi_{t}\right) f\left(z_{t}+\gamma_{t}\right) \tag{2.24}
\end{equation*}
$$

First, we are going to prove that there exists constants $\bar{C}_{\lambda}, \delta_{\lambda}>0$ such that

$$
\begin{equation*}
\frac{d}{2 d t}\left\|z_{t}\right\|^{2} \leq \bar{C}_{\lambda}-\delta_{\lambda}\left\|z_{t}\right\|^{2} \tag{2.25}
\end{equation*}
$$

Indeed, consider two cases.
Case 1: $z_{t}+\gamma_{t} \neq 0$. From assumption $\left(\mathbf{H}_{f}\right)$ and condition (1.10), we can check that

$$
\begin{align*}
\frac{d}{2 d t}\left\|z_{t}\right\|^{2}= & \left\langle z_{t},\left(I d+\psi_{t}\right)\left[\frac{\left\langle z_{t}+\gamma_{t}, f\left(z_{t}+\gamma_{t}\right)\right\rangle}{\left\|z_{t}+\gamma_{t}\right\|^{2}}\left(z_{t}+\gamma_{t}\right)+\pi_{z_{t}+\gamma_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right]\right\rangle \\
= & \underbrace{\left\langle z_{t},\left(I d+\psi_{t}\right) \frac{\left(z_{t}+\gamma_{t}\right)}{\left\|z_{t}+\gamma_{t}\right\|}\right\rangle}_{=: M_{1}} \underbrace{\left\langle\frac{z_{t}+\gamma_{t}}{\left\|z_{t}+\gamma_{t}\right\|}, f\left(z_{t}+\gamma_{t}\right)\right\rangle}_{=: M_{3}} \\
& +\underbrace{\left\langle z_{t}\right.}_{\left.=M_{t},\left(I d+\psi_{t}\right) \pi_{z_{t}+\gamma_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle} . \tag{2.26}
\end{align*}
$$

Observe that from (1.5) and (2.23),

$$
\begin{align*}
& M_{1} \leq\left(1+\left\|\psi_{t}\right\|\right)\left\|z_{t}\right\| \leq(1+\lambda)\left\|z_{t}\right\|  \tag{2.27}\\
& M_{1} \geq\left\langle z_{t}, \frac{z_{t}+\gamma_{t}}{\left\|z_{t}+\gamma_{t}\right\|}\right\rangle-\left\|\psi_{t}\right\|\left\|z_{t}\right\| \geq\left\|z_{t}+\gamma_{t}\right\|-\left\|\gamma_{t}\right\|-\left\|\psi_{t}\right\|\left\|z_{t}\right\| \geq(1-\lambda)\left\|z_{t}\right\|-\lambda  \tag{2.28}\\
& M_{2} \leq D_{1}-D_{2}\left\|z_{t}+\gamma_{t}\right\| \leq D_{1}+D_{2} \lambda-D_{2}\left\|z_{t}\right\| \tag{2.29}
\end{align*}
$$

As a result, (2.27) deduces

$$
\begin{equation*}
M_{1} M_{2} \leq(1+\lambda)\left\|z_{t}\right\| M_{2} \quad \text { if } \quad M_{2} \geq 0 \tag{2.30}
\end{equation*}
$$

while (2.28) follows

$$
\begin{equation*}
M_{1} M_{2} \leq\left[(1-\lambda)\left\|z_{t}\right\|-\lambda\right] M_{2} \quad \text { if } \quad M_{2}<0 \tag{2.31}
\end{equation*}
$$

If $M_{2} \geq 0$ then (2.30) and (2.29) lead to

$$
\begin{equation*}
M_{1} M_{2} \leq(1+\lambda)\left\|z_{t}\right\|\left[D_{1}+D_{2} \lambda-D_{2}\left\|z_{t}\right\|\right] \tag{2.32}
\end{equation*}
$$

If $M_{2}<0$ and $(1-\lambda)\left\|z_{t}\right\|-\lambda \geq 0$, then (2.31) and (2.29) yield

$$
\begin{equation*}
M_{1} M_{2} \leq\left[(1-\lambda)\left\|z_{t}\right\|-\lambda\right]\left[D_{1}+D_{2} \lambda-D_{2}\left\|z_{t}\right\|\right] . \tag{2.33}
\end{equation*}
$$

If $M_{2}<0$ and $(1-\lambda)\left\|z_{t}\right\|-\lambda<0$, then $\left\|z_{t}\right\| \leq \frac{\lambda}{1-\lambda}$ and $\left\|z_{t}+\gamma_{t}\right\| \leq\left\|z_{t}\right\|+\left\|\gamma_{t}\right\| \leq \frac{\lambda}{1-\lambda}+\lambda$. In this case (2.31) and (2.29) deduce

$$
M_{1} M_{2} \leq(1-\lambda)\left\|z_{t}\right\| M_{2}+\lambda\left|M_{2}\right|
$$

$$
\begin{align*}
& \leq(1-\lambda)\left\|z_{t}\right\|\left[D_{1}+D_{2} \lambda-D_{2}\left\|z_{t}\right\|\right]+\lambda\left\|f\left(z_{t}+\gamma_{t}\right)\right\| \\
& \leq(1-\lambda)\left\|z_{t}\right\|\left[D_{1}+D_{2} \lambda-D_{2}\left\|z_{t}\right\|\right]+\lambda \max \left\{\|f(\xi)\|:\|\xi\| \leq \frac{\lambda}{1-\lambda}+\lambda\right\} . \tag{2.34}
\end{align*}
$$

Combining all these three cases $(2.32),(2.33),(2.34)$ and applying Cauchy inequality, we can show that there exists a generic constant $\bar{C}_{\lambda}>0$ such that

$$
M_{1} M_{2} \leq \bar{C}_{\lambda}-\frac{D_{2}}{2}(1-\lambda)\left\|z_{t}\right\|^{2}
$$

On the other hand,

$$
\begin{aligned}
M_{3}= & \left\langle z_{t}+\gamma_{t}, \pi_{z_{t}+h_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle-\left\langle\gamma_{t}, \pi_{z_{t}+h_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle \\
& +\left\langle z_{t}, \psi_{t} \pi_{z_{t}+h_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle \\
= & -\left\langle\gamma_{t}, \pi_{z_{t}+h_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle+\left\langle z_{t}, \psi_{t} \pi_{z_{t}+h_{t}}^{\perp}\left(f\left(z_{t}+\gamma_{t}\right)\right)\right\rangle \\
\leq & \left(\left\|\gamma_{t}\right\|+\left\|\psi_{t}\right\|\left\|z_{t}\right\|\right) C_{f}\left(1+\left\|z_{t}+\gamma_{t}\right\|\right) \\
\leq & \bar{C}_{\lambda}+2 C_{f} \lambda\left\|z_{t}\right\|^{2},
\end{aligned}
$$

for some generic $\bar{C}_{\lambda}$. As a result, there exists a generic constant $\bar{C}_{\lambda}$ such that

$$
\begin{equation*}
\frac{d}{2 d t}\left\|z_{t}\right\|^{2} \leq \bar{C}_{\lambda}+\left[2 C_{f} \lambda-\frac{D_{2}}{2}(1-\lambda)\right]\left\|z_{t}\right\|^{2} . \tag{2.35}
\end{equation*}
$$

Case 2: $z_{t}+\gamma_{t}=0$. Then the same arguments show that

$$
\begin{aligned}
\frac{d}{2 d t}\left\|z_{t}\right\|^{2} & =\left\langle z_{t}+\gamma_{t}, f\left(z_{t}+\gamma_{t}\right)\right\rangle-\left\langle\gamma_{t}, f\left(z_{t}+\gamma_{t}\right)\right\rangle+\left\langle z_{t}, \psi_{t} f\left(z_{t}+\gamma_{t}\right)\right\rangle \\
& =\left\langle z_{t}+\gamma_{t}, f\left(z_{t}+\gamma_{t}\right)\right\rangle-\left\langle\gamma_{t}, f(0)\right\rangle+\left\langle z_{t}, \psi_{t} f(0)\right\rangle \\
& \leq D_{1}\left\|z_{t}+\gamma_{t}\right\|-D_{2}\left\|z_{t}+\gamma_{t}\right\|^{2}+\left(\left\|\gamma_{t}\right\|+\left\|\psi_{t}\right\|\left\|z_{t}\right\|\right)\|f(0)\| \\
& \leq \bar{C}_{\lambda}+\left[2 C_{f} \lambda-\frac{D_{2}}{2}(1-\lambda)\right]\left\|z_{t}\right\|^{2},
\end{aligned}
$$

where one can apply Cauchy inequality to obtain the last inequality for some generic constant $\bar{C}_{\lambda}$. Hence (2.35) holds for all $z_{t} \in \mathbb{R}^{d}$ where $t \in\left[0, \tau \wedge \tau_{\text {local }}\right]$, with a generic constant $\bar{C}_{\lambda}$ and a sufficiently small $\lambda<1$. This proves (2.25) by choosing

$$
\delta_{\lambda}:=\frac{D_{2}}{2}(1-\lambda)-2 C_{f} \lambda>0 \quad \text { for } \quad 0<\lambda<\frac{D_{2}}{D_{2}+4 C_{f}}<1 .
$$

Next, (2.25) implies that $\left\|z_{t}\right\|$ is bounded by $\sqrt{\frac{\bar{C}_{\lambda}}{\delta_{\lambda}}}+\left\|z_{0}\right\|=\sqrt{\frac{\bar{C}_{\lambda}}{\delta_{\lambda}}}+\left\|y_{0}\right\|$ as long as $t \in\left[0, \tau \wedge \tau_{\text {local }}\right]$, thereby proving the existence and uniqueness of the solution $z_{t}$ of equation (2.22) on $\left[0, \tau \wedge \tau_{\text {local }}\right]$, and so is the solution $y_{t}$ of (1.2) on $\left[0, \tau \wedge \tau_{\text {local }}\right]$. In addition, whenever $\tau>\tau_{\text {local }}$ then (2.23) is satisfied and the above arguments can be applied to prove the existence and uniqueness of the solution by concatenation, until the interval $[0, \tau]$ is fully covered.

Finally, with such $\lambda>0$, construct a greedy sequence of stopping times $\left\{\tau_{i}\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x},[0, t]\right)\right\}$. On each interval $\left[\tau_{i}, \tau_{i+1}\right]$ it is similar to prove the existence and uniqueness of the solution of the two differential equations (1.2) and (2.22) with the shifted time

$$
\begin{aligned}
d y_{t+\tau_{i}} & =f\left(y_{t+\tau_{i}}\right) d t+g\left(y_{t+\tau_{i}}\right) d x_{t+\tau_{i}}, \quad \forall t \in\left[0, \tau_{i+1}-\tau_{i}\right] ; \\
\dot{z}_{t+\tau_{i}} & =\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}_{\cdot+\tau_{i}}, z_{t+\tau_{i}}\right)\right]^{-1} f\left(\phi_{t}\left(\mathbf{x}_{\cdot+\tau_{i}}, z_{t+\tau_{i}}\right)\right), \quad \forall t \in\left[0, \tau_{i+1}-\tau_{i}\right] .
\end{aligned}
$$

As a result, the existence and uniqueness of the solution of the two systems (1.2) and (2.22) on $[0, T]$ is proved by concatenation. To estimate the solution norm, observe from (2.35) that

$$
\begin{aligned}
& \qquad \begin{array}{l}
\left\|z_{t}\right\| \leq \sqrt{\frac{\bar{C}_{\lambda}}{\delta_{\lambda}}}+\left\|z_{\tau_{i}}\right\| \exp \left\{-\delta_{\lambda}\left(t-\tau_{i}\right)\right\}, \quad \forall t \in\left[\tau_{i}, \tau_{i+1}\right], i \in \mathbb{N} . \\
\text { In particular, }\left\|y_{\tau_{i+1}}\right\|
\end{array} \frac{\lambda}{2}+\sqrt{\frac{\bar{C}_{\lambda}}{\delta_{\lambda}}}+\left\|y_{\tau_{i}}\right\| \exp \left\{-\delta_{\lambda}\left(\tau_{i+1}-\tau_{i}\right)\right\}, \quad \forall i \in \mathbb{N} \text {. }
\end{aligned}
$$

Assign $C_{\lambda}:=\frac{\lambda}{2}+\sqrt{\frac{\bar{C}_{\lambda}}{\delta_{\lambda}}}$. By induction, one can easily show that

$$
\left\|y_{\tau_{i}}\right\| \leq\left\|y_{0}\right\| \exp \left\{-\delta_{\lambda} \tau_{i}\right\}+i C_{\lambda}, \quad \forall i \in \mathbb{N}
$$

By the definition of stopping times (2.10), $\tau_{N\left(\frac{\lambda}{16 C_{p C g}}, \mathbf{x},[0, t]\right)}=t$, which deduces (2.21).

## 3 Random attractors

### 3.1 Generation of random dynamical systems

In this subsection we would like to present the generation of a random dynamical system from rough differential equation (1.2), which is based mainly on the work in [2] with only a small modification for Hölder spaces. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space equipped with a so-called measurable metric dynamical system $\theta: \mathbb{R} \times \Omega \rightarrow \Omega$ such that $\theta_{t}: \Omega \rightarrow \Omega$ is $\mathbb{P}$ - preserving, i.e $\mathbb{P}(B)=\mathbb{P}\left(\theta_{t}^{-1}(B)\right)$ for all $B \in \mathcal{F}, t \in \mathbb{R}$, and $\theta_{t+s}=\theta_{t} \circ \theta_{s}$ for all $t, s \in \mathbb{R}$. A continuous random dynamical system $\varphi: \mathbb{R} \times \Omega \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d},\left(t, \omega, y_{0}\right) \mapsto \varphi(t, \omega) y_{0}$ is then defined as a measurable mapping which is also continuous in $t$ and $y_{0}$ such that the cocycle property

$$
\begin{equation*}
\varphi(t+s, \omega) y_{0}=\varphi\left(t, \theta_{s} \omega\right) \circ \varphi(s, \omega) y_{0}, \quad \forall t, s \in \mathbb{R}, \omega \in \Omega, y_{0} \in \mathbb{R}^{d} \tag{3.1}
\end{equation*}
$$

is satisfied [1].
In our setting, denote by $T_{1}^{2}\left(\mathbb{R}^{m}\right)=1 \oplus \mathbb{R}^{m} \oplus\left(\mathbb{R}^{m} \otimes \mathbb{R}^{m}\right)$ the set with the tensor product

$$
\left(1, g^{1}, g^{2}\right) \otimes\left(1, h^{1}, h^{2}\right)=\left(1, g^{1}+h^{1}, g^{1} \otimes h^{1}+g^{2}+h^{2}\right),
$$

for all $\mathbf{g}=\left(1, g^{1}, g^{2}\right), \mathbf{h}=\left(1, h^{1}, h^{2}\right) \in T_{1}^{2}\left(\mathbb{R}^{m}\right)$. Then it can be shown that $\left(T_{1}^{2}\left(\mathbb{R}^{m}\right), \otimes\right)$ is a topological group with unit element $\mathbf{1}=(1,0,0)$ and $\mathbf{g}^{-1}=\left(1,-g^{1}, g^{1} \otimes g^{1}-g^{2}\right)$.

Given $\alpha \in\left(\frac{1}{3}, \nu\right)$, denote by $C^{0, \alpha}\left(I, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ the closure of $C^{\infty}\left(I, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ in the Hölder space $C^{\alpha}\left(I, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$, and by $C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ the space of all paths $\left.\mathbf{g}: \mathbb{R} \rightarrow T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ such that $\left.\mathbf{g}\right|_{I} \in$ $C^{0, \alpha}\left(I, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ for each compact interval $I \subset \mathbb{R}$ containing 0 . Then $C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ is equipped with the compact open topology given by the $\alpha$ - Hölder norm (2.2), i.e the topology generated by the metric

$$
d_{\alpha}(\mathbf{g}, \mathbf{h}):=\sum_{k \geq 1} \frac{1}{2^{k}}\left(\|\mathbf{g}-\mathbf{h}\|_{\alpha,[-k, k]} \wedge 1\right) .
$$

As a result, it is separable and thus a Polish space.
Let us consider a stochastic process $\overline{\mathbf{X}}$ defined on a probability space $(\bar{\Omega}, \overline{\mathcal{F}}, \overline{\mathbb{P}})$ with realizations in $\left(C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right), \mathcal{F}\right)$. Assume further that $\overline{\mathbf{X}}$ has stationary increments. Assign $\Omega:=$ $C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$ and equip it with the Borel $\sigma$ - algebra $\mathcal{F}$ and let $\mathbb{P}$ be the law of $\overline{\mathbf{X}}$. Denote by $\theta$ the Wiener-type shift

$$
\begin{equation*}
\left(\theta_{t} \omega\right) .=\omega_{t}^{-1} \otimes \omega_{t+\cdot}, \forall t \in \mathbb{R}, \omega \in C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right) \tag{3.2}
\end{equation*}
$$

and define the so-called diagonal process $\mathbf{X}: \mathbb{R} \times \Omega \rightarrow T_{1}^{2}\left(\mathbb{R}^{m}\right), \mathbf{X}_{t}(\omega)=\omega_{t}$ for all $t \in \mathbb{R}, \omega \in \Omega$. Due to the stationarity of $\overline{\mathbf{X}}$, it can be proved that $\theta$ is invariant under $\mathbb{P}$, then forming a continuous (and thus measurable) dynamical system on $(\Omega, \mathcal{F}, \mathbb{P})[2$, Theorem 5]. Moreover, $\mathbf{X}$ forms an $\alpha-$ rough path cocycle, namely, $\mathbf{X}(\omega) \in C_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right.$ ) for every $\omega \in \Omega$, which satisfies the cocyle relation:

$$
\mathbf{X}_{t+s}(\omega)=\mathbf{X}_{s}(\omega) \otimes \mathbf{X}_{t}\left(\theta_{s} \omega\right), \forall \omega \in \Omega, t, s \in \mathbb{R}
$$

in the sense that $\mathbf{X}_{s, s+t}=\mathbf{X}_{t}\left(\theta_{s} \omega\right)$ with the increment notation $\mathbf{X}_{s, s+t}:=\mathbf{X}_{s}^{-1} \otimes \mathbf{X}_{s+t}$. It is important to note that the two-parameter flow property

$$
\mathbf{X}_{s, u} \otimes \mathbf{X}_{u, t}=\mathbf{X}_{s, t}, \forall s, t \in \mathbb{R}
$$

is equivalent to the fact that $\mathbf{X}_{t}(\omega)=\left(1, \mathbf{x}_{t}(\omega)\right)=\left(1, x_{t}(\omega), \mathbb{X}_{0, t}(\omega)\right)$, where $x .(\omega): \mathbb{R} \rightarrow \mathbb{R}^{m}$ and $\mathbb{X}_{.,}(\omega): I^{2} \rightarrow \mathbb{R}^{m} \otimes \mathbb{R}^{m}$ are random funtions satisfying Chen's relation relation (2.3).

To fulfill the Hölder continuity of almost all realizations, assume condition (1.8) that the estimate $\mathbb{E}\left(\left\|x_{s, t}\right\|^{p}+\left\|\mathbb{X}_{s, t}\right\|^{q}\right) \leq C_{T, \nu}|t-s|^{p \nu}$ holds for all $s, t \in[0, T]$ and any interval $[0, T]$, with $p \nu \geq 1, q=\frac{p}{2}$ and some constant $C_{T, \nu}$. Then due to the Kolmogorov criterion for rough paths [14, Appendix A.3], for any $\alpha \in\left(\frac{1}{3}, \nu\right)$ and $p=\frac{1}{\alpha}$, there exists a version of $\omega$-wise $(x, \mathbb{X})$ and random variables $K_{\beta} \in$ $L^{p}, \mathbb{K}_{\beta} \in L^{q}$, such that, $\omega$-wise speaking and an abuse of notation, $\left\|x_{s, t}\right\| \leq K_{\alpha}|t-s|^{\alpha}, \quad\left\|\mathbb{X}_{s, t}\right\| \leq$ $\mathbb{K}_{\alpha}|t-s|^{2 \alpha}$, for all $s, t \in[0, T]$, so that $\mathbf{x}=(x, \mathbb{X}) \in \mathscr{C}^{\alpha}(I)$. Moreover, we could modify $\alpha$ such that

$$
\begin{gathered}
x \in C^{0, \alpha}(I):=\left\{x \in C^{\alpha}(I): \lim _{\Delta \rightarrow 0} \sup _{0<t-s<\Delta} \frac{\left\|x_{s, t}\right\|}{|t-s|^{\alpha}}=0\right\} \\
\mathbb{X} \in C^{0,2 \alpha}\left(I^{2}\right):=\left\{\mathbb{X} \in C^{2 \alpha}\left(I^{2}\right): \lim _{\Delta \rightarrow 0} \sup _{0<t-s<\Delta} \frac{\left\|\mathbb{X}_{s, t}\right\|}{|t-s|^{2 \alpha}}=0\right\},
\end{gathered}
$$

thus $\mathscr{C}^{0, \alpha}(I) \subset C^{0, \alpha}(I) \oplus C^{0,2 \alpha}\left(I^{2}\right)$ is separable due to the separability of $C^{0, \alpha}(I)$ and $C^{0,2 \alpha}\left(I^{2}\right)$. In particular, the Wiener shift (3.2) implies that

$$
\begin{equation*}
\left\|\mathbf{x}\left(\theta_{h} \omega\right)\right\|_{p-\operatorname{var},[s, t]}=\|\mathbf{x}(\omega)\|_{p-\operatorname{var},[s+h, t+h]}, N_{[s, t]}\left(\mathbf{x}\left(\theta_{h} \omega\right)\right)=N_{[s+h, t+h]}(\mathbf{x}(\omega)) \tag{3.3}
\end{equation*}
$$

Remark 3.1 Due to [2, Corollary 9], the above construction is possible for $X_{t}$ to be a continuous, centered Gaussian process with stationary increments and independent components, satisfying: there exists for any $T>0$ a constant $C_{T}$ such that for all $p \geq \frac{1}{\bar{\nu}}, \mathbb{E}\left\|X_{t}-X_{s}\right\|^{p} \leq C_{T}|t-s|^{p \nu}$ for all $s, t \in[0, T]$. Then $\mathbf{X}$ can be chosen to be the natural lift of $X$ in the sense of Friz-Victoir [14, Chapter 15] with sample paths in the space $\mathscr{C}_{0}^{0, \alpha}\left(\mathbb{R}, T_{1}^{2}\left(\mathbb{R}^{m}\right)\right)$, for a certain $\alpha \in(0, \nu)$.

For example, consider $X$ to be an $m$ - dimensional fractional Brownian motion $B^{H}$ with independent components [32] and Hurst exponent $H \in\left(\frac{1}{3}, 1\right)$, i.e. a family of $B^{H}=\left\{B_{t}^{H}\right\}_{t \in \mathbb{R}}$ with continuous sample paths and $\mathbb{E}\left[B_{t}^{H} B_{s}^{H}\right]=\frac{1}{2}\left(t^{2 H}+s^{2 H}-|t-s|^{2 H}\right) I^{m \times m}$, for all $t, s \in \mathbb{R}_{+}$. Given a fixed interval $[0, T]$, the covariance of increments of fractional Brownian motions $R:[0, T]^{4} \rightarrow \mathbb{R}^{m \times m}$, defined by $R\left(\begin{array}{cc}s & t \\ s^{\prime} & t^{\prime}\end{array}\right):=E\left(B_{s, t}^{H} B_{s^{\prime}, t^{\prime}}^{H}\right)$ is of finite $\varrho-$ variation norm for $\varrho=\frac{1}{2 H}$, i.e.

$$
\|R\|_{I \times I^{\prime}, \varrho}:=\left\{\sup _{\Pi(I), \Pi^{\prime}\left(I^{\prime}\right)} \sum_{\substack{[s, t] \in \Pi(I),\left[s^{\prime}, t^{\prime}\right] \in \Pi\left(I^{\prime}\right)}}\left|R\left(\begin{array}{cc}
s & t  \tag{3.4}\\
s^{\prime} & t^{\prime}
\end{array}\right)\right|^{\varrho}\right\}^{\frac{1}{\varrho}}<\infty
$$

and there exists a constant $M_{\varrho, T}$ such that $\|R\|_{[s, t]^{2}, \varrho} \leq M_{\varrho, T}|t-s|^{\frac{1}{\varrho}}, \quad \forall t, s \in[0, T]$.
Then one can prove that the integral

$$
\mathbb{X}_{s, t}^{i, j}=\lim _{|\Pi| \rightarrow 0} \int_{\Pi} X_{s, r}^{i} d X_{r}^{j}=\lim _{|\Pi| \rightarrow 0} \sum_{[u, v] \in \Pi} X_{s, u}^{i} X_{u, v}^{j} \quad \text { in } \mathcal{L}^{2} \text { - sense, } \quad \forall s, t \in[0, T]
$$

is well-defined regardless of the chosen partition $\Pi$ of $[s, t]$; in addition $\mathbb{X}_{s, t}^{i, i}=\frac{1}{2}\left(X_{s, t}^{i}\right)^{2}$ and $\mathbb{X}_{s, t}^{i, j}+$ $\mathbb{X}_{s, t}^{j, i}=X_{s, t}^{i} X_{s, t}^{j}$. Furthermore, for $\frac{1}{p}<\nu<\frac{1}{2 \varrho}=H$, there exist constants $C(p, \varrho, m, T), C(p, \varrho, m, T, \nu)$ such that

$$
\begin{aligned}
\mathbb{E}\left[\left\|X_{s, t}\right\|^{p}+\left\|\mathbb{X}_{s, t}\right\|^{q}\right] & \leq C(p, \varrho, m, T)|t-s|^{p H}, \quad \forall s, t \in[0, T] \quad \text { and } \\
\mathbb{E}\left[\|X\|_{\nu,[0, T]}^{p}+\|\mathbb{X}\|_{2 \nu,[0, T]}^{q}\right] & \leq C(p, \varrho, m, T, \nu) M_{\varrho, T}^{q} .
\end{aligned}
$$

Therefore for $\frac{1}{3}<\alpha<\nu<H$, almost sure all realizations $\mathbf{x}=(X, \mathbb{X})$ belong to the set $\mathscr{C}^{0, \alpha}([0, T])$ and satisfy Chen's relation (2.3) and satisfy condition (1.8).

We reformulate the conclusion in [2, Theorem 21] in our scenarios as follows.
Proposition 3.2 Given the measurable metric dynamical system $(\Omega, \mathscr{F}, \mathbb{P}, \theta)$ and the $p$ - rough cocycle $\mathbf{X}: \mathbb{R} \times \Omega \rightarrow T_{1}^{2}\left(\mathbb{R}^{m}\right)$ as above, the system (1.1) generates a continuous random dynamical system $\varphi$ over $(\Omega, \mathscr{F}, \mathbb{P}, \theta)$, such that for any $[0, T]$ and all $\omega \in \Omega, \varphi(t, \omega) y_{0}$ is the unique solution (in the Gubinelli sense) of (1.2), which is understood in the pathwise integral form (2.9) on $[0, T]$, where $\mathbf{x}=(x, \mathbb{X})$ is the projection of $\mathbf{X} .(\omega)$ on $\mathbb{R}^{m} \oplus\left(\mathbb{R}^{m} \otimes \mathbb{R}^{m}\right)$.

Proof: For the benefit of the reader, we present here a sketch of the proof. Fix a realization $\omega \in \Omega$ of the diagonal process $\mathbf{X}$, then $\omega_{t}=\mathbf{X}_{t}(\omega)=\left(1, x_{t}(\omega), \mathbb{X}_{0, t}(\omega)\right)$. Since $\mathbf{X}$ is a rough cocycle, the shift property (3.2) yields

$$
\begin{equation*}
\left(1, x_{u, v}(\omega), \mathbb{X}_{u, v}(\omega)\right)=\omega_{u}^{-1} \otimes \omega_{v}=\left(\theta_{u} \omega\right)_{v-u}, \quad \forall 0 \leq u \leq v \tag{3.5}
\end{equation*}
$$

We therefore can rewrite the definition of the rough integral as

$$
\begin{equation*}
\int_{a}^{b} y_{u} d \omega_{u}:=\lim _{|\Pi| \rightarrow 0} \sum_{\Pi} \underbrace{\left(y_{u} \otimes x_{u, v}(\omega)+y_{u}^{\prime} \mathbb{X}_{u, v}(\omega)\right)}_{=:\left(y_{u}, y_{u}^{\prime}\right) \bar{\otimes}\left(1, x_{u, v}(\omega), \mathbb{X}_{u, v}(\omega)\right)}=\lim _{|\Pi| \rightarrow 0} \sum_{\Pi}\left(y_{u}, y_{u}^{\prime}\right) \bar{\otimes}\left(\theta_{u} \omega\right)_{v-u} \tag{3.6}
\end{equation*}
$$

where the operator $\bar{\otimes}$ is well defined. Because $\theta_{u+r} \omega=\theta_{u} \circ \theta_{r} \omega$, it is easy to check that the rough integral in (3.6) satisfies the additivity and the shift properties, i.e.

$$
\begin{align*}
\int_{a}^{c} y_{u} d \omega_{u} & =\int_{a}^{b} y_{u} d \omega_{u}+\int_{b}^{c} y_{u} d \omega_{u}, \quad \forall a \leq b \leq c  \tag{3.7}\\
\int_{a+r}^{b+r} y_{u} d \omega_{u} & =\int_{a}^{b} y_{u+r} d\left(\theta_{r} \omega\right)_{u}, \quad \forall a \leq b, r \in \mathbb{R} . \tag{3.8}
\end{align*}
$$

These two properties (3.7), (3.8) and Theorem 2.2 then suffice to prove the cocycle property (3.1) of the generated random dynamical system from stochastic rough differential equation (1.1).

### 3.2 Existence of random attractors

Given a random dynamical system $\varphi$ on the phase space $\mathbb{R}^{d}$, we follow [8] (see also [9], [1, Chapter 9] and the references therein) to present the notion of random pullback attractors. Recall that a set $\hat{M}:=\{M(\omega)\}_{\omega \in \Omega}$ is a random set, if $\omega \mapsto d(y \mid M(\omega)):=\inf \{d(y, z) \mid z \in M(\omega)\}$ is $\mathscr{F}$-measurable for each $y \in \mathbb{R}^{d}$. An universe $\mathscr{D}$ is a family of random sets which is closed w.r.t. inclusions (i.e. if $\hat{D}_{1} \in \mathscr{D}$ and $\hat{D}_{2} \subset \hat{D}_{1}$ then $\left.\hat{D}_{2} \in \mathscr{D}\right)$. In our setting, we define the universe $\mathscr{D}$ to be a family of tempered random sets $D(\omega)$, which means the following: A random variable $\rho(\omega)>0$ is called tempered if it satisfies $\lim _{t \rightarrow \pm \infty} \frac{1}{t} \log ^{+} \rho\left(\theta_{t} \omega\right)=0$ a.s. (see e.g. [1, pp. 164, 386]) which is equivalent
to the sub-exponential growth $\lim _{t \rightarrow \pm \infty} e^{-c|t|} \rho\left(\theta_{t} \omega\right)=0$ a.s. for all $\left.c>0[28, \mathrm{p} .220]\right)$. A random set $D(\omega)$ is called tempered if it is contained in a ball $B(0, \rho(\omega))$ a.s., where the radius $\rho(\omega)$ is a tempered random variable.

A random subset $A$ is called invariant, if $\varphi(t, \omega) A(\omega)=A\left(\theta_{t} \omega\right)$ for all $t \in \mathbb{R}, \omega \in \Omega$. An invariant random compact set $\mathcal{A} \in \mathscr{D}$ is called a pullback attractor in $\mathscr{D}$, if $\mathcal{A}$ attracts any closed random set $\hat{D} \in \mathscr{D}$ in the pullback sense, i.e.

$$
\begin{equation*}
\lim _{t \rightarrow \infty} d_{H}\left(\varphi\left(t, \theta_{-t} \omega\right) \hat{D}\left(\theta_{-t} \omega\right) \mid \mathcal{A}(\omega)\right)=0 \tag{3.9}
\end{equation*}
$$

where $d_{H}(\cdot \mid \cdot)$ is the Hausdorff semi-distance, i.e. $d_{H}(D \mid A):=\sup _{d \in D} \inf _{a \in A}\|d-a\|$. $\mathcal{A}$ is called a forward attractor in $\mathscr{D}$, if $\mathcal{A}$ is invariant and attracts any closed random set $\hat{D} \in \mathscr{D}$ in the forward sense, i.e. $\lim _{t \rightarrow \infty} d_{H}\left(\varphi(t, \omega) \hat{D}(x) \mid \mathcal{A}\left(\theta_{t} \omega\right)\right)=0$.

The existence of a pullback attractor follows from the existence of a pullback absorbing set (see [9, Theorem 3]), namely a random set $\mathcal{B} \in \mathscr{D}$ is called pullback absorbing in the universe $\mathscr{D}$ if $\mathcal{B}$ absorbs all closed random sets in $\mathscr{D}$, i.e. for any closed random set $\hat{D} \in \mathscr{D}$, there exists a time $t_{0}=t_{0}(\omega, \hat{D})$ such that

$$
\begin{equation*}
\varphi\left(t, \theta_{-t} \omega\right) \hat{D}\left(\theta_{-t} \omega\right) \subset \mathcal{B}(\omega), \text { for all } t \geq t_{0} \tag{3.10}
\end{equation*}
$$

Then given the universe $\mathscr{D}$ and a compact pullback absorbing set $\mathcal{B} \in \mathscr{D}$, there exists a unique pullback attractor $\mathcal{A}(\omega)$ in $\mathscr{D}$, given by

$$
\begin{equation*}
\mathcal{A}(\omega)=\bigcap_{t \geq 0} \overline{\bigcup_{s \geq t} \varphi\left(s, \theta_{-s} \omega\right) \mathcal{B}\left(\theta_{-s} \omega\right)} . \tag{3.11}
\end{equation*}
$$

Our first main result is formulated as follows.
Theorem 3.3 Under the assumptions $\left(\boldsymbol{H}_{f}\right),\left(\boldsymbol{H}_{g}\right),\left(\boldsymbol{H}_{X}\right)$, there exists a pullback attractor $\mathcal{A}(\omega)$ for the generated random dynamical system of the stochastic system (1.1) such that $|\mathcal{A}(\cdot)| \in \mathcal{L}^{\rho}$ for any $\rho \geq 1$.

Proof: First (2.21) and Jensen's inequality deduce that, for any $\rho \geq 1$ there exists an $\eta \in(0,1)$ and an integrable random variable $\xi_{1}(\omega)=\xi_{1}\left(C_{g}\|\mathbf{x}(\omega)\|_{p-\mathrm{var},[0,1]}\right)$ such that

$$
\begin{equation*}
\left\|y_{1}\right\|^{\rho} \leq \eta\left\|y_{0}\right\|^{\rho}+\xi_{1}(\omega) . \tag{3.12}
\end{equation*}
$$

From (3.12) it is easy to prove by induction that

$$
\left\|y_{n}\left(\mathbf{x}, y_{0}\right)\right\|^{\rho} \leq \eta^{n}\left\|y_{0}\right\|^{\rho}+\sum_{i=0}^{n-1} \eta^{i} \xi_{1}\left(\theta_{n-i} \omega\right), \quad \forall n \geq 1
$$

thus replacing $\omega$ by $\theta_{-n} \omega$ yields

$$
\left\|y_{n}\left(\theta_{-n} \omega, y_{0}\left(\theta_{-n} \omega\right)\right)\right\|^{\rho} \leq \eta^{n}\left\|y_{0}\left(\theta_{-n} \omega\right)\right\|^{\rho}+\sum_{i=0}^{\infty} \eta^{i} \xi_{1}\left(\theta_{-i} \omega\right) .
$$

In other words, starting from a tempered random set $D(\omega) \in \mathscr{D}$ which is contained in a ball $B(0, r(\omega))$ with a tempered random radius $r(\omega)$, then any point $y_{0}=y_{0}\left(\theta_{-t} \omega\right) \in D\left(\theta_{-t} \omega\right)$ satisfies

$$
\begin{align*}
& \left\|y_{n}\left(\theta_{-n} \omega, y_{0}\left(\theta_{-n} \omega\right)\right)\right\|^{\rho} \leq \eta^{n} r\left(\theta_{-n} \omega\right)^{\rho}+\underbrace{\sum_{i=0}^{\infty} \eta^{i} \xi_{1}\left(\theta_{-i} \omega\right)}_{=: R(\omega)} \\
\Rightarrow & \left.\| \varphi\left(n, \theta_{-n} \omega\right) D\left(\theta_{-n} \omega\right)\right) \|^{\rho} \leq \eta^{n} r\left(\theta_{-n} \omega\right)^{\rho}+R(\omega) . \tag{3.13}
\end{align*}
$$

Due to the integrability of $\xi_{1}, R$ is also integrable (and thus tempered) with $\mathbb{E} R(\cdot)=\frac{1}{1-\eta} \mathbb{E} \xi_{1}(\cdot)$. On the other hand, the cocycle property (3.1) yields

$$
\begin{equation*}
\varphi\left(t+n, \theta_{-t-n} \omega\right) D\left(\theta_{-t-n} \omega\right)=\varphi\left(n, \theta_{-n} \omega\right) \circ \varphi\left(t, \theta_{-t-n} \omega\right) D\left(\theta_{-t-n} \omega\right), \forall t \in[0,1] \tag{3.14}
\end{equation*}
$$

It follows from (2.21) and the shift property (3.3) that

$$
\begin{align*}
\left\|\varphi\left(t, \theta_{-t-n} \omega\right) y\left(\theta_{-t-n} \omega\right)\right\| & \leq\left\|y\left(\theta_{-t-n} \omega\right)\right\|+C_{\lambda} N\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x}\left(\theta_{-t-n} \omega\right),[0, t]\right) \\
& \leq r\left(\theta_{-t-n} \omega\right)+C_{\lambda} N\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x}\left(\theta_{-n} \omega\right),[-1,0]\right) \tag{3.15}
\end{align*}
$$

for all $t \in[0,1]$ and $n \in \mathbb{N}$. Since the right hand side of (3.15) is a tempered random variable, we conclude from (3.13), (3.14) and (3.15) that there exists a pullback absorbing set $\mathcal{B}(\omega)=B(0, \hat{b}(\omega))$, with a tempered random variable $\hat{b}(\omega)=[1+R(\omega)]^{\frac{1}{\rho}}$, containing our pullback attractor $\mathcal{A}(\omega)$. In particular, $|\mathcal{A}(\cdot)| \in \mathcal{L}^{\rho}$.

Our second main result shows the existence and the upper-semi continuity of the pullback attractor in comparison to the deterministic attractor, under the additional Lipschitz continuity assumption (1.11) for the drift $f$ and the uniform attraction assumption $\left(\mathbf{H}_{\mathcal{A}}\right)$ for $\mathcal{A}$. Note that the Doss-Sussmann technique and the method in Theorem 2.2 do not work in this case because $C_{\lambda}$ still contains $D_{1}$ and can not be arbitrarily small for sufficiently small $C_{g}$, thus we will provide a direct proof.

Theorem 3.4 Assume that $f$ is globally Lipschitz continuous with (1.11) and dissipative in the relative sense, i.e. there exists $D_{1}, D_{2}>0$ such that

$$
\begin{equation*}
\left\langle y_{1}-y_{2}, f\left(y_{1}\right)-f\left(y_{2}\right)\right\rangle \leq D_{1}-D_{2}\left\|y_{1}-y_{2}\right\|^{2}, \quad \forall y_{1}, y_{2} \in \mathbb{R}^{d} . \tag{3.16}
\end{equation*}
$$

Then under the assumptions $\left(\boldsymbol{H}_{g}\right),\left(\boldsymbol{H}_{\mathcal{X}}\right),\left(\boldsymbol{H}_{\mathcal{A}}\right)$, the random attractor is upper semi-continuous, i.e.

$$
\begin{equation*}
\lim _{\bar{C}_{g} \rightarrow 0} d_{H}(\mathcal{A}(\omega) \mid \mathcal{A})^{\rho}=0 \quad \text { a.s. } \quad \text { and } \quad \lim _{\bar{C}_{g} \rightarrow 0} \mathbb{E} d_{H}(\mathcal{A}(\cdot) \mid \mathcal{A})^{\rho}=0, \quad \forall \rho \geq 1 \tag{3.17}
\end{equation*}
$$

Proof: Fix any solution $y_{t}\left(\mathbf{x}, y_{0}\right)$ and associate it with the solution $\mu_{t}\left(\mu_{0}\right)$ of the deterministic system $\dot{\mu}=\bar{f}(\mu)$ which starts at $\mu_{0}$. Consider the difference $y_{t}^{*}:=y_{t}-\mu_{t}$ for $t \geq 0$, then $y^{*}$ satisfies the equation

$$
d y_{t}^{*}=\left[f\left(y_{t}^{*}+\mu_{t}\right)-f\left(\mu_{t}\right)\right] d t+g\left(y_{t}^{*}+\mu_{t}\right) d x_{t}=\bar{f}\left(y_{t}^{*}\right) d t+\bar{g}\left(y_{t}^{*}\right) d x_{t} .
$$

First, we prove that there exists a constant $\eta \in(0,1)$ and an integrable random variable $\xi_{1}(\omega)$ such that

$$
\begin{equation*}
\left\|y_{r}^{*}\right\|^{\rho} \leq \eta\left\|y_{0}^{*}\right\|^{\rho}+\xi_{1}(\omega) . \tag{3.18}
\end{equation*}
$$

holds for a certain instant $r>0$. Consider the difference $\mu_{t}^{*}=\mu_{t}\left(y_{0}\right)-\mu_{t}\left(\mu_{0}\right)$ of the two solutions of the deterministic system (1.4) starting at different points $y_{0}$ and $\mu_{0}$, then $\mu_{t}^{*}$ is the solution of the nonautonomous deterministic system $\frac{d}{d t} \mu_{t}^{*}=f\left(\mu_{t}^{*}+\mu_{t}\right)-f\left(\mu_{t}\right)$ which starts at $\mu_{0}^{*}=y_{0}^{*}$. The relative dissipativity assumption (3.16) yields $\left\|\mu_{t}^{*}\right\| \leq \frac{D_{1}}{D_{2}}+\left\|\mu_{0}^{*}\right\|$ and

$$
\begin{equation*}
\left\|\mu_{s, t}^{*}\right\| \leq \int_{s}^{t} L_{f}\left\|\mu_{u}^{*}\right\| d u \leq L_{f}\left(1+\frac{D_{1}}{D_{2}}\right)\left(1+\left\|y_{0}^{*}\right\|\right)(t-s), \quad \forall 0 \leq s<t \leq r \tag{3.19}
\end{equation*}
$$

thus $\mu^{*} \in C^{1-\mathrm{var}}$. Moreover, because $\left(\mathbf{H}_{\mathcal{A}}\right)$ is fulfilled with certain numbers $r, D_{3}$, we can choose $\mu_{0}$ depending on $y_{0}$ such that (1.13) is satisfied, i.e.

$$
\begin{equation*}
\left\|\mu_{r}^{*}\right\| \leq\left\|\mu_{0}^{*}\right\| e^{-D_{2} r} \tag{3.20}
\end{equation*}
$$

Assign $h_{t}:=y_{t}^{*}-\mu_{t}^{*}$, then $h$ satisfies

$$
\begin{equation*}
h_{s, t}=\int_{s}^{t}\left[f\left(h_{u}+\mu_{u}+\mu_{u}^{*}\right)-f\left(\mu_{u}+\mu_{u}^{*}\right)\right] d u+\int_{s}^{t} g\left(h_{u}+\mu_{u}+\mu_{u}^{*}\right) d x_{u} \tag{3.21}
\end{equation*}
$$

thus $h$ is also controlled by $x$ with $h_{s}^{\prime}=y_{s}^{\prime}=g\left(h_{s}+\mu_{s}+\mu_{s}^{*}\right)$ and $R_{s, t}^{h}=R_{s, t}^{y}-\mu_{s, t}-\mu_{s, t}^{*}$. We need an auxiliary result below.

Proposition 3.5 There exists a generic constant $D$ such that the following estimate holds

$$
\begin{align*}
\left\|h_{r}\right\| & \leq \xi_{0}(\mathbf{x})\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right), \quad \text { where }  \tag{3.22}\\
\xi_{0}(\mathbf{x}) & :=e^{4 L_{f} r}\left(1+4 C_{p} r\|f\|_{\infty, \mathcal{A}}+4 C_{p} D\right) 8 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[0, r]} N\left(\frac{1}{8 C_{p} C_{g}}, \mathbf{x},[0, r]\right)
\end{align*}
$$

Assume that (3.22) in Proposition 3.5 holds, we then apply Jensen's inequality and Young inequality, for $\epsilon>0$ small enough, and use (3.20) to conclude that

$$
\begin{aligned}
& \left\|y_{r}^{*}\right\|^{\rho} \\
\leq & \left(\left\|h_{r}\right\|+\left\|\mu_{r}^{*}\right\|\right)^{\rho} \leq(1+\epsilon)^{\rho-1}\left\|\mu_{r}^{*}\right\|^{\rho}+\left(\frac{1+\epsilon}{\epsilon}\right)^{\rho-1}\left\|h_{r}\right\|^{\rho} \\
\leq & (1+\epsilon)^{\rho-1}\left\|y_{0}^{*}\right\|^{\rho}\left(e^{-D_{2}}\right)^{\rho}+\left(\frac{1+\epsilon}{\epsilon}\right)^{\rho-1}\left[(1+\epsilon)^{\rho-1} \xi_{0}(\mathbf{x})^{\rho}\left\|y_{0}^{*}\right\|^{\rho \beta}+\left(\frac{1+\epsilon}{\epsilon}\right)^{\rho-1} \xi_{0}(\mathbf{x})^{\rho}\right] \\
\leq & (1+\epsilon)^{\rho-1}\left\|y_{0}^{*}\right\|^{\rho} e^{-\rho D_{2}}+\left(\frac{1+\epsilon}{\epsilon}\right)^{2 \rho-2} \xi_{0}(\mathbf{x})^{\rho} \\
& +\left(\frac{1+\epsilon}{\epsilon}\right)^{\rho-1}(1+\epsilon)^{\rho-1}\left[\beta\left(\epsilon^{\rho \beta}\left\|y_{0}^{*}\right\|^{\rho \beta}\right)^{\frac{1}{\beta}}+(1-\beta)\left(\frac{1}{\epsilon^{\rho \beta}} \xi_{0}(\mathbf{x})^{\rho}\right)^{\frac{1}{1-\beta}}\right] \\
\leq & (1+\epsilon)^{2(\rho-1)}\left(e^{-\rho D_{2}}+\epsilon \beta\right)\left\|y_{0}^{*}\right\|^{\rho}+\xi_{1}(\mathbf{x})
\end{aligned}
$$

where

$$
\begin{equation*}
\xi_{1}(\mathbf{x})=\left(\frac{1+\epsilon}{\epsilon}\right)^{\rho-1}(1+\epsilon)^{\rho-1}(1-\beta)\left(\frac{1}{\epsilon^{\rho \beta}} \xi_{0}(\mathbf{x})^{\rho}\right)^{\frac{1}{1-\beta}}+\left(\frac{1+\epsilon}{\epsilon}\right)^{2 \rho-2} \xi_{0}(\mathbf{x})^{\rho} \tag{3.23}
\end{equation*}
$$

Note that $\xi_{1}(\mathbf{x}(\omega))=\xi_{1}(\omega)$ is integrable in $\omega$ due to the assumption. By choosing $\epsilon \in(0,1)$ small enough such that

$$
\eta:=(1+\epsilon)^{2(\rho-1)}\left[e^{-\rho D_{2}}+\epsilon \beta\right]<1
$$

we obtain (3.18).
Next, the same arguments as in the proof of Theorem 3.3 for discrete times $n r$ lead to

$$
\begin{align*}
& \left\|y_{n}\left(\theta_{-n} \omega, y_{0}\left(\theta_{-n} \omega\right)\right)-\mu_{n}\left(\mu_{0}\right)\right\|^{\rho} \leq \eta^{n}\left(\left\|y_{0}\left(\theta_{-n} \omega\right)\right\|+\left\|\mu_{0}\right\|\right)^{\rho}+\underbrace{\sum_{i=0}^{\infty} \eta^{i} \xi_{1}\left(\theta_{-i} \omega\right)}_{=: R(\omega)} \\
& \Rightarrow d_{H}\left(\varphi_{n}\left(\theta_{-n} \omega, D\left(\theta_{-n} \omega\right)\right) \mid \mathcal{A}\right)^{\rho} \leq \eta^{n}\left(\left|D\left(\theta_{-n} \omega\right)\right|+|\mathcal{A}|\right)^{\rho}+R(\omega) \tag{3.24}
\end{align*}
$$

The final argument in the proof of Theorem 3.3 is then applied to prove that there exists a pullback absorbing set $\mathcal{B}(\omega)=B(0, \hat{b}(\omega))$, with a tempered random variable $\hat{b}(\omega)=|\mathcal{A}|+[1+R(\omega)]^{\frac{1}{\rho}}$, containing our pullback attractor $\mathcal{A}(\omega)$. In particular, choose $D(\omega)=\mathcal{A}(\omega)$ (which is naturally tempered) and let $n$ tends to infinity in the inequality (3.24), then the first term in the right hand side of (3.24) tends to zero due to the temperedness of $\mathcal{A}(\omega)$ and we obtain

$$
\begin{equation*}
d_{H}(\mathcal{A}(\omega) \mid \mathcal{A})^{\rho} \leq R(\omega) \tag{3.25}
\end{equation*}
$$

Now because

$$
\begin{aligned}
& 8 C_{p} C_{g}\|\mathrm{x}\|_{p-\mathrm{var},[0, r]} N\left(\frac{1}{8 C_{p} C_{g}}, \mathbf{x},[0, r]\right) \\
\leq & 8 C_{p} C_{g}\|\mathrm{x}\|_{p-\mathrm{var},[0, r]}\left[1+\left(8 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[0, r]}\right)^{p}\right] \rightarrow 0
\end{aligned}
$$

as $C_{g} \rightarrow 0$, both in the almost sure and in the $\mathcal{L}^{\rho}$ senses, the definitions of $\xi_{0}(\omega)$ in (3.22) and of $\xi_{1}(\omega)$ in (3.23) show that $R(\omega) \rightarrow 0$ as $C_{g} \rightarrow 0$, both in the almost sure and in the $\mathcal{L}^{\rho}$ senses. This proves (3.17).

Proof: [Proof of Proposition 3.5] First, it follows from (3.21) that

$$
\begin{align*}
\left\|h_{s, t}\right\| \leq & \int_{s}^{t} L_{f}\left\|h_{u}\right\| d u+C_{g}\left\|x_{s, t}\right\|+C_{g}^{2}\left\|\mathbb{X}_{s, t}\right\|  \tag{3.26}\\
& +C_{p}\left\{\|\mathbb{X}\|_{q-\mathrm{var},[s, t]^{2}}\left\|[g(y)]^{\prime}\right\|_{p-\mathrm{var},[s, t]}+\|x\|_{p-\mathrm{var},[s, t]}\| \| R^{g(y)} \|_{q-\mathrm{var},[s, t]^{2}}\right\} .
\end{align*}
$$

Observe that for $\beta=\frac{2}{p} \in\left(\frac{2}{3}, 1\right)$,

$$
\begin{aligned}
& \left\|g\left(\mu_{u}+h_{u}+\mu_{u}^{*}\right)-g\left(\mu_{v}+h_{v}+\mu_{v}^{*}\right)\right\| \vee\left\|D g\left(\mu_{u}+h_{u}+\mu_{u}^{*}\right)-D g\left(\mu_{v}+h_{v}+\mu_{v}^{*}\right)\right\| \\
\leq & C_{g}\left\|h_{u, v}\right\|+C_{g}\left\|\mu_{u, v}\right\|+2 C_{g}\left\|\mu_{u, v}^{*}\right\|^{\beta} \\
\leq & C_{g}\left\|h_{u, v}\right\|+C_{g}\left\|\mu_{u, v}\right\|+C_{g} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)(t-s)^{\beta}, \quad \forall 0 \leq u<v \leq r,
\end{aligned}
$$

for a generic constant $D$. This follows that

$$
\begin{align*}
& \left\|g\left(\mu+h+\mu^{*}\right)\right\|_{p-\operatorname{var},[s, t]} \vee\left\|D g\left(\mu+h+\mu^{*}\right)\right\|_{p-\mathrm{var},[s, t]}  \tag{3.27}\\
\leq & C_{g}\|h\|_{p-\mathrm{var},[s, t]}+C_{g}\|\mu\|_{1-\mathrm{var},[s, t]}+C_{g} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)(t-s)^{\beta}, \quad \forall 0 \leq s<t \leq r .
\end{align*}
$$

Inequality (3.27) together with $[g(y)]_{s}^{\prime}=D g\left(y_{s}\right) g\left(y_{s}\right)$ leads to

$$
\begin{equation*}
\left\|[g(y)]^{\prime}\right\|_{p-\operatorname{var},[s, t]} \leq 2 C_{g}^{2}\left(\|h\|_{p-\operatorname{var},[s, t]}+\|\mu\|_{1-\mathrm{var},[s, t]}+D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)\right), \tag{3.28}
\end{equation*}
$$

for all $0 \leq s<t \leq r$. Furthermore,

$$
\begin{aligned}
\left\|R_{s, t}^{g(y)}\right\|= & \left\|g\left(y_{s}+h_{s}^{\prime} x_{s, t}+R_{s, t}^{h}+\mu_{s, t}+\mu_{s, t}^{*}\right)-g\left(y_{s}\right)-D g\left(y_{s}\right) g\left(y_{s}\right) x_{s, t}\right\| \\
\leq & \left\|g\left(y_{s}+g\left(y_{s}\right) x_{s, t}+R_{s, t}^{h}+\mu_{s, t}+\mu_{s, t}^{*}\right)-g\left(y_{s}+g\left(y_{s}\right) x_{s, t}\right)\right\| \\
& +\left\|g\left(y_{s}+g\left(y_{s}\right) x_{s, t}\right)-g\left(y_{s}\right)-D g\left(y_{s}\right) g\left(y_{s}\right) x_{s, t}\right\| \\
\leq & C_{g}\left\|R_{s, t}^{h}\right\|+C_{g}\left\|\mu_{s, t}\right\|+2 C_{g}\left\|\mu_{s, t}^{*}\right\|^{\beta} \\
& +\int_{0}^{1}\left\|D_{g}\left(y_{s}+\chi g\left(y_{s}\right) x_{s, t}\right)-D g\left(y_{s}\right)\right\|\left\|g\left(y_{s}\right)\right\|\left\|x_{s, t}\right\| d \chi \\
\leq & C_{g}\left\|R_{s, t}^{h}\right\|+C_{g}\left\|\mu_{s, t}\right\|+C_{g} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)(t-s)^{\beta}+\frac{1}{2} C_{g}^{3}\left\|x_{s, t}\right\|^{2},
\end{aligned}
$$

for all $0 \leq s<t \leq r$, which, due to $\beta q=\beta \frac{p}{2}=1$, yields

$$
\begin{align*}
\left\|R^{g(y)}\right\|_{q-\mathrm{var},[s, t]^{2}} \leq & C_{g}\left\|R^{h}\right\|_{q-\mathrm{var},[s, t]^{2}}+C_{g}\|\mu\|_{1-\mathrm{var},[s, t]} \\
& +C_{g} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)+\frac{1}{2} C_{g}^{3}\|x\|_{p-\mathrm{var},[s, t]}^{2} \tag{3.29}
\end{align*}
$$

for all $0 \leq s<t \leq r$. Replacing (3.28) and (3.29) into (3.26) we obtain

$$
\begin{aligned}
& \|h\|_{p-\mathrm{var},[s, t]} \\
\leq & \int_{s}^{t} L_{f}\left\|h_{u}\right\| d u+C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}+C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}^{2}+\frac{1}{2} C_{p} C_{g}^{3}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}^{3} \\
& +2 C_{p}\left(C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}^{2} \vee C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}\right)\left(\|\mu\|_{1-\mathrm{var},[s, t]}+D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)\right) \\
& +2 C_{p}\left(C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}^{2} \vee C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}\right)\left\|h, R^{h}\right\|_{p-\mathrm{var},[s, t]}, \quad \forall 0 \leq s<t \leq r .
\end{aligned}
$$

The estimate for $R^{h}$ is already included in the right hand side of the above inequality (excluded the term $\left.C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[\mathrm{s}, t]}\right)$. Since $\left\|h_{u}\right\| \leq\left\|h_{s}\right\|+\left\|h, R^{h}\right\|_{p-\mathrm{var},[s, u]}$, we finally obtain

$$
\begin{align*}
& \left\|h, R^{h}\right\|_{p-\mathrm{var},[s, t]} \\
= & \|h\|_{p-\mathrm{var},[s, t]}+\left\|R^{h}\right\|_{q-\mathrm{var},[s, t]^{2}} \\
\leq & \int_{s}^{t} 2 L_{f}\left(\left\|h_{s}\right\|+\left\|h h, R^{h}\right\|_{p-\mathrm{var},[s, u]}\right) d u \\
& +\left(C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}+2 C_{g}^{2}\|\mathbf{x}\|_{p-\operatorname{var},[s, t]}^{2}+C_{p} C_{g}^{3}\left\|\mathbf{x}^{2}\right\|_{p-\mathrm{var},[s, t]}^{3}\right) \times \\
& \times\left(1+4 C_{p}\|\mu\|_{1-\mathrm{var},[s, t]}+4 C_{p} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)\right) \\
& +4 C_{p}\left(C_{g}^{2}\| \| \mathbf{x}\left\|_{p-\mathrm{var},[s, t]}^{2} \vee C_{g}\right\| \mathbf{x} \|_{p-\mathrm{var},[s, t]}\right)\left\|h, R^{h}\right\|_{p-\operatorname{var},[s, t]} \\
\leq & \int_{s}^{t} 2 L_{f}\left(\left\|h_{s}\right\|+\left\|h, R^{h}\right\|_{p-\operatorname{var},[s, u]}\right) d u+\frac{1}{2}\left\|h h, R^{h}\right\|_{p-\mathrm{var},[s, t]} \\
& +\underbrace{4 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}\left(1+4 C_{p}\|\mu\|_{1-\mathrm{var},[s, t]}+4 C_{p} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)\right.}_{=: L_{1}}) \tag{3.30}
\end{align*}
$$

whenever $4 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]} \leq \frac{1}{2}$. Estimate (3.30) yields

$$
\left\|h_{s}\right\|+\left\|h, R^{h}\right\|_{p-\mathrm{var},[s, t]} \leq\left\|h_{s}\right\|+2 L_{1}+\int_{s}^{t} 4 L_{f}\left(\left\|h_{s}\right\|+\left\|h, R^{h}\right\|_{p-\mathrm{var},[s, u]}\right) d u
$$

whenever $4 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]} \leq \frac{1}{2}$, thus by the continuous Gronwall lemma,

$$
\left\|h_{s}\right\|+\left\|h, R^{h}\right\|_{p-\operatorname{var},[s, t]} \leq\left(\left\|h_{s}\right\|+2 L_{1}\right) e^{4 L_{f}(t-s)}
$$

whenever $4 C_{p} C_{g}\| \| \|_{p-\mathrm{var},[s, t]} \leq \frac{1}{2}$. Now by constructing the greedy sequence of stopping times of the form $\left\{\tau_{i}\left(\frac{1}{8 C_{p} C_{g}}, \mathbf{x},[s, t]\right)\right\}_{i \in \mathbb{N}}$ as in (2.10), we can prove by induction that

$$
\|h\|_{\infty,\left[\tau_{k}, \tau_{k-1}\right]} \leq e^{4 L_{f}\left(\tau_{k}-s\right)}\left(\left\|h_{s}\right\|+2 L_{1} k\right), \quad \forall k=1, \ldots, N\left(\frac{1}{8 C_{p} C_{g}}, \mathbf{x},[s, t]\right)
$$

This enables us to show that

$$
\begin{align*}
\|h\|_{\infty,[s, t]} \leq e^{4 L_{f}(t-s)}\left\{\left\|h_{s}\right\|+\right. & N\left(\frac{1}{8 C_{p} C_{g}}, \mathbf{x},[s, t]\right) 8 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}  \tag{3.31}\\
& \left.\times\left(1+4 C_{p}\|\mu\|_{1-\mathrm{var},[s, t]}+4 C_{p} D\left(1+\left\|y_{0}^{*}\right\|^{\beta}\right)\right)\right\},
\end{align*}
$$

for all $0 \leq s<t \leq r$. Since $h_{0}=y_{0}^{*}-\mu_{0}^{*}=0$ and $\|\mu\|_{1-\operatorname{var},[0, r]} \leq r\|f\|_{\infty, \mathcal{A}}$ due to (1.12), (3.22) is proved.

If $f$ is strictly dissipative, i.e. $D_{1}=0$ in condition (3.16), then (1.5) is automatically satisfied and the attractor $\mathcal{A}$ is a singleton. However, it is not a trivial task to prove that $\mathcal{A}(\omega)$ is a singleton random attractor. In fact, we can only prove below that statement for sufficiently small $C_{g}$.

From now on, we follow the terminologies in the proof of Theorem 2.2 with

$$
\gamma_{t}=y_{t}-z_{t} ; \quad \bar{\gamma}_{t}=\bar{y}_{t}-\bar{z}_{t} ; \quad \psi_{t}=\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1}-I d ; \quad \bar{\psi}_{t}=\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, \bar{z}_{t}\right)\right]^{-1}-I d .
$$

Also from the proof of Theorem 2.2, given a time $\tau>0$ such that $16 C_{p} C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[0, \tau]} \leq \lambda$ where $\lambda<\frac{D_{2}}{D_{2}+4 C_{f}}$, it follows that $N\left(\frac{1}{16 C_{p} C_{g}}, \mathbf{x},[0, t]\right)=1$ for all $t \in[0, \tau]$. We first need an auxiliary result.

Proposition 3.6 Assume $\left(\boldsymbol{H}_{g}\right),\left(\boldsymbol{H}_{X}\right)$ and $\lambda, \tau$ as introduced above. Then there exist an increasing continuous function $K:[0,1] \rightarrow \mathbb{R}_{+}$with $K(0)=0$, such that the following estimates hold

$$
\begin{equation*}
\left\|\bar{\gamma}_{t}-\gamma_{t}\right\| \leq \lambda\left\|\bar{z}_{t}-z_{t}\right\| ; \quad\left\|\bar{\psi}_{t}-\psi_{t}\right\| \leq K(\lambda)\left\|\bar{z}_{t}-z_{t}\right\|, \quad \forall t \in[0, \tau] . \tag{3.32}
\end{equation*}
$$

Proof: i, The proof for the first estimate is simple, since one can write $\bar{\gamma}_{t}-\gamma_{t}$ in the form

$$
\bar{\gamma}_{t}-\gamma_{t}=\int_{0}^{t}\left[g\left(\bar{\phi}_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right)-g\left(\phi_{u}\left(\mathbf{x}, z_{t}\right)\right)\right] d x_{u} .
$$

Then the estimates (2.17) and (2.18) together with (2.14), (2.15) enable us to obtain

$$
\begin{align*}
&\left\|\bar{\gamma}_{t}-\gamma_{t}\right\| \\
& \leq\left\|g\left(\bar{z}_{t}\right)-g\left(z_{t}\right)\right\|\|x\|_{p-\operatorname{var},[0, t]}+\left\|D g\left(\bar{z}_{t}\right) g\left(\bar{z}_{t}\right)-D g\left(z_{t}\right) g\left(z_{t}\right)\right\|\|\mathbb{X}\|_{q-\operatorname{var},[0, t]^{2}} \\
&+C_{p}\left\{\|x\|_{p-\operatorname{var},[0, t]}\left\|R^{g(\bar{\phi})-g(\phi)}\right\|_{q-\mathrm{var},[0, t]^{2}}\right. \\
&\left.\quad+\|\mathbb{X}\|_{q-\mathrm{var},[0, t]^{2}}\left\|[g(\bar{\phi})-g(\phi)]^{\prime}\right\|_{p-\mathrm{var},[0, t]}\right\} \\
& \leq 2 C_{p}\left\{C_{g}\|\mathbf{x}\|_{p-\mathrm{var},[0, t]}+C_{g}^{2}\| \| \mathbf{x} \|_{p-\mathrm{var},[0, t]}^{2}\right\} \\
& \times\left(1+\left\|\bar{\phi}, R^{\bar{\phi}}\right\|_{p-\mathrm{var},[0, t]}+\left\|\phi, R^{\phi}\right\|_{p-\mathrm{var},[0, t]}\right) \\
& \times\left(\left\|\bar{z}_{t}-z_{t}\right\|+\left\|\bar{\phi}-\phi, R^{\bar{\phi}-\phi}\right\|_{p-\operatorname{var},[0, t]}\right) \\
& \leq 2 C_{p}\left\{C_{g}\|\mathbf{x}\|_{p-\operatorname{var},[0, t]}+C_{g}^{2}\|\mathbf{x}\|_{p-\mathrm{var},[0, t]]}^{2}\right\}\left(1+16 C_{p} C_{g}\|\mathbf{x}\|_{p-\operatorname{var},[0, t]}\right)^{2}\left\|\bar{z}_{t}-z_{t}\right\| \\
& \leq \frac{\lambda}{4}(1+\lambda)^{2}\left\|\bar{z}_{t}-z_{t}\right\| \leq \lambda\left\|\bar{z}_{t}-z_{t}\right\|, \quad \forall t \in[0, \tau] . \tag{3.33}
\end{align*}
$$

ii, The proof for the second estimate in (3.32) is more technical and lengthy. First observe from (2.19) that

$$
\begin{aligned}
\left\|\bar{\psi}_{t}-\psi_{t}\right\| & =\left\|\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, \bar{z}_{t}\right)\right]^{-1}-\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1}\right\| \\
& \leq\left\|\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, \bar{z}_{t}\right)\right]^{-1}\right\|\left\|\left[\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right]^{-1}\right\|\left\|\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, \bar{z}_{t}\right)-\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right\| \\
& \leq(1+\lambda)^{2}\left\|\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, \bar{z}_{t}\right)-\frac{\partial \phi}{\partial z}\left(t, \mathbf{x}, z_{t}\right)\right\|, \quad \forall t \in[0, \tau] ;
\end{aligned}
$$

hence it is enough to estimate the last term in the right hand side of the above inequality. We will write in short $\left\|\bar{\xi}_{t}-\xi_{t}\right\|$ for some $t \in[0, \tau]$ fixed, so that $\bar{z}_{t}$ and $z_{t}$ are also fixed as well. By definition
$\bar{\xi}_{t}$ and $\xi_{t}$ are respectively the values at time $t$ of the solutions $\bar{\xi}_{u}\left(\mathbf{x}, \bar{z}_{t}\right)$ and $\xi_{u}\left(\mathbf{x}, z_{t}\right)$ of the linear matrix - valued rough differential equations

$$
\bar{\xi}_{v}=I d+\int_{0}^{v} D g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right) \bar{\xi}_{u} d x_{u} ; \quad \xi_{v}=I d+\int_{0}^{v} D g\left(\phi_{u}\left(\mathbf{x}, z_{t}\right)\right) \xi_{u} d x_{u}
$$

As a result,

$$
\begin{align*}
\underbrace{\bar{\xi}_{v}-\xi_{v}}_{=: \zeta_{v}}= & \int_{0}^{v} \underbrace{D g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right)}_{=: A_{u}} \underbrace{\left(\bar{\xi}_{u}-\xi_{u}\right)}_{=: \zeta_{u}} d x_{u} \\
& +\int_{0}^{v} \underbrace{\left[D g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right)-D g\left(\phi_{u}\left(\mathbf{x}, z_{t}\right)\right)\right]}_{=: b_{u}} \xi_{u} d x_{u} . \tag{3.34}
\end{align*}
$$

It follows from (3.34) that $\zeta_{0}=0$ and

$$
\begin{aligned}
\left\|\zeta_{u, v}\right\|= & \left\|\int_{u}^{v} A_{\chi} \zeta_{\chi} d x_{\chi}\right\|+\underbrace{\left\|\int_{u}^{v} b_{\chi} \xi_{\chi} d x_{\chi}\right\|}_{=: \Lambda u, v} \\
\leq & \left\|A_{u}\right\|\left\|\zeta_{u}\right\|\|x\|_{p-\operatorname{var},[u, v]}+\left\|A_{u} \otimes A_{u}\right\|\left\|\zeta_{u}\right\|\|\mathbb{X}\|_{q-\mathrm{var},[u, v]}+\Lambda_{u, v} \\
& +C_{p}\left\{\|x\|_{p-\mathrm{var},[u, v]}\left\|R^{A \zeta}\right\|_{q-\mathrm{var},[u, v]}\right. \\
& \left.\quad+\|\mathbb{X}\|_{q-\mathrm{var},[u, v]}\left\|\left(A^{\prime}+A \otimes A\right) \zeta\right\|_{p-\mathrm{var},[u, v]}\right\}
\end{aligned}
$$

Since

$$
A_{v} \zeta_{v}-A_{u} \zeta_{u}=\left(A_{u}^{\prime} \zeta_{u}+A_{u} \zeta_{u}^{\prime}\right) x_{u, v}+R_{u, v}^{A} \zeta_{u}+A_{u} R_{u, v}^{\zeta}+A_{u, v} \zeta_{u, v},
$$

$\zeta$ and $A \zeta$ are controlled by $x$ with $\zeta_{u}^{\prime}=A_{u} \zeta_{u},(A \zeta)_{u}^{\prime}=A_{u}^{\prime} \zeta_{u}+A_{u} \otimes A_{u} \zeta_{u}$ and

$$
\begin{aligned}
&\left\|\left(A^{\prime}+A \otimes A\right) \zeta\right\|_{p-\operatorname{var},[u, v]} \leq\left\|A^{\prime}+A \otimes A\right\|_{p-\operatorname{var},[u, v]}\|\zeta\|_{\infty,[u, v]} \\
&+\left\|A^{\prime}+A \otimes A\right\|_{\infty,[u, v]}\|\zeta\|_{p-\operatorname{var},[u, v]} \\
& \leq 2\left(\left\|A^{\prime}\right\|_{p-\operatorname{var},[u, v]}+2\|A\|_{p-\operatorname{var},[u, v]}^{2}\right)\|\zeta\|_{p-\operatorname{var},[u, v]} ; \\
& \| R_{u, v}^{A \zeta \| \leq} \leq\left\|R_{u, v}^{A}\right\|\left\|\zeta_{u}\right\|+\left\|A_{u}\right\|\left\|R_{u, v}^{\zeta}\right\|+\left\|A_{u, v}\right\|\left\|\zeta_{u, v}\right\| ; \\
&\left\|R^{A \zeta \|_{q-\operatorname{var},[u, v]} \leq}\right\|\left\|R^{A}\right\|_{q-\operatorname{var},[u, v]}\|\zeta\|_{\infty,[u, v]}+\|A\|_{\infty,[u, v]}\left\|R^{\zeta}\right\|_{q-\operatorname{var},[u, v]} \\
&+\|A\|_{p-\operatorname{var},[u, v]}\|\zeta\|_{p-\operatorname{var},[u, v]} \\
& \leq\left(\left\|A_{u}\right\|+\left\|A, R^{A}\right\|_{p-\operatorname{var},[u, v]}\right)\left(\left\|\zeta_{u}\right\|+\left\|\zeta, R^{\zeta}\right\|_{p-\operatorname{var},[u, v]}\right) .
\end{aligned}
$$

Because $A_{u}=D g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right)$, a direct computation shows that $A_{u}^{\prime}=D^{2} g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right) g\left(\phi_{u}\left(\mathbf{x}, \bar{z}_{t}\right)\right)$ with

$$
\begin{aligned}
\|A\|_{p-\operatorname{var},[u, v]} & \leq C_{g}\left(1+\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)\right\|_{p-\operatorname{var},[u, v]}\right) \\
\left\|A^{\prime}\right\|_{p-\operatorname{var},[u, v]} & \leq C_{g}^{2}\left(1+2\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)\right\|_{p-\operatorname{var},[u, v]}\right) \\
\left\|R^{A}\right\|_{q-\operatorname{var},[u, v]} & \leq C_{g}\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)\right\|_{p-\operatorname{var},[u, v]}^{2}+C_{g}\left\|R^{\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)}\right\|_{q-\operatorname{var},[u, v]} .
\end{aligned}
$$

As a result, by combining all the above estimates and using (2.14), we can show that there exists a generic function $D(\lambda) \geq 1$ such that

$$
\|\zeta\|_{p-\mathrm{var},[u, v]} \leq\|\Lambda\|_{p-\mathrm{var},[u, v]}+C_{p}\left(C_{g}\|x\|_{p-\mathrm{var},[u, v]} \vee C_{g}^{2}\|\mathrm{x}\|_{q-\mathrm{var},[u, v]}^{2}\right)
$$

$$
\times D(\lambda)\left(\left\|\zeta_{u}\right\|+\left\|\zeta, R^{\zeta}\right\|_{p-\mathrm{var},[u, v]}\right)
$$

The estimate for $\left\|\left\|R^{\zeta}\right\|_{q-\mathrm{var},[u, v]}\right.$ is already included in the above estimate, hence

$$
\begin{aligned}
\left\|\zeta, R^{\zeta}\right\|_{p-\mathrm{var},[u, v]} \leq & 2\|\Lambda\|_{p-\mathrm{var},[u, v]}+2 C_{p} D(\lambda)\left(C_{g}\|x\|_{p-\mathrm{var},[u, v]} \vee C_{g}^{2}\| \|_{\mathbf{x}_{q-\mathrm{var},[u, v]}}^{2}\right) \\
& \times\left(\left\|\zeta_{u}\right\|+\left\|\zeta, R^{\zeta}\right\|_{p-\mathrm{var},[u, v]}\right), \quad \forall 0 \leq u<v \leq t
\end{aligned}
$$

This implies

$$
\begin{aligned}
&\left\|\zeta_{v}\right\| \leq\left\|\zeta_{u}\right\|+\left\|\zeta, R^{\zeta}\right\| \|_{p-\mathrm{var},[u, v]} \leq 2\|\Lambda\|_{p-\mathrm{var},[0, t]}+2\left\|\zeta_{u}\right\| \\
& \text { whenever } \quad\|\mathbf{x}\|_{p-\mathrm{var},[u, v]} \leq \underbrace{\left[4 C_{p} C_{g} D(\lambda)\right]^{-1}}_{=: \lambda^{\prime}}
\end{aligned}
$$

By constructing the stopping times $\left\{\tau_{i}\left(\lambda^{\prime}, \mathbf{x},[0, t]\right)\right\}$ and using induction, we can show that

$$
\begin{align*}
\left\|\zeta_{t}\right\| & \leq \exp \left\{N\left(\lambda^{\prime}, \mathbf{x},[0, t]\right) \log 2\right\}\left(\left\|\zeta_{0}\right\|+2\|\Lambda\|_{p-\mathrm{var},[0, t]}\right) \\
& \leq 2\|\Lambda\|_{p-\mathrm{var},[0, t]} \exp \left\{N\left(\lambda^{\prime}, \mathbf{x},[0, t]\right) \log 2\right\} \tag{3.35}
\end{align*}
$$

It remains to estimate $\|\Lambda \Lambda\|_{p-\mathrm{var},[0, t]}$. Observe that

$$
\begin{aligned}
\left\|\Lambda_{u, v}\right\| \leq & \left\|b_{u} \xi_{u}\right\|\|x\|_{p-\operatorname{var},[u, v]}+\left\|(b \xi)_{u}^{\prime}\right\|\|\mathbb{X}\|_{q-\operatorname{var},[u, v]} \\
& +C_{p}\left(\|x\|_{p-\mathrm{var},[u, v]}\left\|R^{b \xi}\right\|_{q-\mathrm{var},[u, v]}+\|\mathbb{X}\|_{q-\mathrm{var},[u, v]}\| \|(b \xi)^{\prime} \|_{p-\mathrm{var},[u, v]}\right)
\end{aligned}
$$

which yields

$$
\begin{aligned}
& \|\Lambda\|_{p-\operatorname{var},[0, t]} \\
& \leq\|b\|_{\infty,[0, t]}\|\xi\|_{\infty,[0, t]}\|\mathbf{x}\|_{p-\operatorname{var},[0, t]} \\
& +\left(\left\|b^{\prime}\right\|_{\infty,[0, t]}\|\xi\|_{\infty,[0, t]}+\|b\|_{\infty,[0, t]}\left\|\xi^{\prime}\right\|_{\infty,[0, t]}\right)\|\mathbf{x}\|_{q-\mathrm{var},[0, t]}^{2} \\
& +C_{p}\|\mathbf{x}\|_{p-\mathrm{var},[0, t]}\left(\left\|b_{0}\right\|+\left\|b, R^{b}\right\|_{p-\mathrm{var},[0, t]}\right)\left(\left\|\xi_{0}\right\|+\left\|\xi, R^{\xi}\right\|_{p-\mathrm{var},[0, t]}\right) \\
& +C_{p}\|\mathbf{x}\|_{q-\operatorname{var},[0, t]}^{2}\left\{\left\|b^{\prime}\right\|_{p-\operatorname{var},[0, t]}\|\xi\|_{\infty,[0, t]}+\left\|b^{\prime}\right\|_{\infty,[0, t]}\|\xi\|_{p-\operatorname{var},[0, t]}\right. \\
& \left.+\left\|\xi^{\prime}\right\|\left\|_{p-\operatorname{var},[0, t]}\right\| b\left\|_{\infty,[0, t]}+\right\| \xi^{\prime}\left\|_{\infty,[0, t]}\right\| b \|_{p-\mathrm{var},[0, t]}\right\} .
\end{aligned}
$$

It is easy to check from (2.19) that the estimates for $\left\|\left\|\xi, R^{\xi}\right\|_{p-\mathrm{var},[0, t]},\right\| \xi^{\prime} \|_{p-\mathrm{var},[0, t]}$ and $\|\xi\|_{\infty,[0, t]},\left\|\xi^{\prime}\right\|_{\infty,[0, t]}$ are functions of $16 C_{p} C_{g}\|\mathbf{x}\|_{p-\operatorname{var},[0, t]}$ and can thus be bounded from above by functions of $\lambda$. On the other hand, similar to the computations in Proposition 2.1, we can show that

$$
\begin{aligned}
\|b\|_{\infty,[0, t]} & \leq C_{g}\left\|\bar{\phi} \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{\infty,[0, t]} \\
\left\|b^{\prime}\right\|_{\infty,[0, t]} \leq & \leq D^{2} g\left(\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)\right) g\left(\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)\right)-D^{2} g\left(\phi \cdot\left(\mathbf{x}, z_{t}\right)\right) g\left(\phi \cdot\left(\mathbf{x}, z_{t}\right)\right) \|_{\infty,[0, t]} \\
\|b\|_{p-\mathrm{var},[0, t]} \leq & C_{g}\left(\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{p-\mathrm{var},[0, t]}\right. \\
& \left.\quad+\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{\infty,[0, t]}\left\|\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{p-\mathrm{var},[0, t]}\right)
\end{aligned}
$$

$$
\begin{align*}
\left\|b^{\prime}\right\|_{p-\operatorname{var},[0, t]} \leq & C_{g}\left(\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{p-\mathrm{var},[0, t]}\right. \\
& \left.\quad+\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{\infty,[0, t]]}\left\|\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{p-\operatorname{var},[0, t]}\right) \\
\left\|R^{b}\right\|_{q-\operatorname{var},[0, t]} \leq & C_{g}\left\|R^{\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)}\right\|_{q-\mathrm{var},[0, t]} \\
& +C_{g}\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{\infty,[0, t]}\left\|R^{\phi \cdot\left(\mathbf{x}, z_{t}\right)}\right\|_{q-\operatorname{var},[0, t]} \\
& +\frac{1}{2} C_{g}^{2}\|\mathbf{x}\|_{p-\operatorname{var},[0, t]}\left[\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{p-\operatorname{var},[0, t]}\right. \\
& \left.+\left\|\phi \cdot\left(\mathbf{x}, \bar{z}_{t}\right)-\phi \cdot\left(\mathbf{x}, z_{t}\right)\right\|_{\infty,[0, t]}\left(\|\bar{\phi}\|_{p-\operatorname{var},[0, t]}+\|\phi\|_{p-\operatorname{var},[0, t]}\right)\right] . \tag{3.36}
\end{align*}
$$

Finally, the existence of function $K$ satisfying (3.32) is a consequence of (3.35), (3.36) and the estimates $(2.14),(2.16),(2.15)$ on $[0, \tau]$, which can be written as functions of $\lambda$.

Theorem 3.7 (Singleton attractor) Assume $\left(\boldsymbol{H}_{f}\right),\left(\boldsymbol{H}_{g}\right),\left(\boldsymbol{H}_{X}\right)$ and further that $f \in C^{1}$ is strictly dissipative (i.e. $D_{1}=0$ in condition (3.16)). Then for $C_{g}$ small enough the random attractor $\mathcal{A}$ is a singleton, i.e. $\mathcal{A}(\omega)=\{a(\omega)\}$ a.s., thus it satisfies the upper semi-continuity (3.17).

Proof: We first prove that for any $\lambda<\frac{D_{2}}{2\left(D_{2}+C_{f}\right)}$, there exists a random variable $0<\Delta(\lambda, \omega) \in$ $\mathcal{L}^{1}$ such that for any two solutions $\bar{y}_{t}$ and $y_{t}$ of system (1.2) starting respectively from $\bar{y}_{0}, y_{0} \in \mathcal{A}(\omega)$, the following estimate holds

$$
\begin{equation*}
\left\|\bar{y}_{1}-y_{1}\right\| \leq \exp \left\{-D_{2}+\Delta(\lambda, \mathbf{x}(\omega))\right\}\left\|\bar{y}_{0}-y_{0}\right\| . \tag{3.37}
\end{equation*}
$$

Indeed, given $\tau>0$ as above, assign $\eta_{t}:=\bar{z}_{t}-z_{t}$ and consider the equation

$$
\begin{aligned}
\dot{\eta}_{t} & =\left(I d+\bar{\psi}_{t}\right) f\left(\bar{z}_{t}+\bar{\gamma}_{t}\right)-\left(I d+\psi_{t}\right) f\left(z_{t}+\gamma_{t}\right) \\
& =\left[f\left(\bar{y}_{t}\right)-f\left(y_{t}\right)\right]+\bar{\psi}_{t}\left[f\left(\bar{y}_{t}\right)-f\left(y_{t}\right)\right]+\left(\bar{\psi}_{t}-\psi_{t}\right) f\left(y_{t}\right) .
\end{aligned}
$$

It follows from Lagrange's mean value theorem, the strict dissipativity, estimates (2.21) and (3.32) that for all $t \in[0, \tau]$,

$$
\begin{aligned}
& \frac{d}{d t}\left\|\eta_{t}\right\|^{2} \\
& \leq 2\left\langle\bar{y}_{t}-y_{t}-\left(\bar{\gamma}_{t}-\gamma_{t}\right), f\left(\bar{y}_{t}\right)-f\left(y_{t}\right)\right\rangle+2\left\|\eta_{t}\right\|\left\|\bar{\psi}_{t}-\psi_{t}\right\|\left\|f\left(y_{t}\right)\right\| \\
&+2\left\|\eta_{t}\right\|\left\|\bar{\psi}_{t}\right\|\left\|f\left(\bar{y}_{t}\right)-f\left(y_{t}\right)\right\| \\
& \leq-2 D_{2}\left\|\bar{y}_{t}-y_{t}\right\|^{2}+2\left\|\eta_{t}\right\|\left\|\bar{\psi}_{t}-\psi_{t}\right\| \underbrace{}_{=:\|f\|_{\infty, \mathcal{A}\left(\theta_{t} \omega\right)}^{\max \left\{\left\|f\left(p_{1}\right)\right\|: p_{1} \in \mathcal{A}\left(\theta_{t} \omega\right)\right\}}} \\
&+2\left(\left\|\bar{\gamma}_{t}-\gamma_{t}\right\|+\left\|\bar{\psi}_{t}\right\|\left\|\eta_{t}\right\|\right) \underbrace{\leq}_{=:\|D f\|_{\infty, B\left(0,\left|\mathcal{A}\left(\theta_{t} \omega\right)\right|\right)}^{\max \left\{\left\|D f\left(p_{1}\right)\right\|:\left\|p_{1}\right\| \leq\left|\mathcal{A}\left(\theta_{t} \omega\right)\right|\right\}}\left\|\bar{y}_{t}-y_{t}\right\|} \\
& \leq-2 D_{2}\left\|\eta_{t}\right\|^{2}(1-\lambda)+2\|f\|_{\infty, \mathcal{A}\left(\theta_{t} \omega\right)} K(\lambda)\left\|\eta_{t}\right\|^{2}+4\|D f\|_{\infty, B\left(0,\left|\mathcal{A}\left(\theta_{t} \omega\right)\right|\right)}(1+\lambda) \lambda\left\|\eta_{t}\right\|^{2} \\
& \leq 2\{D_{2}-\underbrace{\left(1+\|D f\|_{\infty, B\left(0,\left|\mathcal{A}\left(\theta_{t} \omega\right)\right|\right)}^{\left(1+\|f\|_{\infty, \mathcal{A}\left(\theta_{t} \omega\right)}\right)}\right.}_{=: G(\lambda)} \\
&\quad \times \underbrace{\left[D_{2} \lambda+2(1+\lambda) \lambda+K(\lambda)\right]}_{=:\left(\theta_{t} \omega\right)}\}\left\|\eta_{t}\right\|^{2} .
\end{aligned}
$$

As a result $\left\|\eta_{\tau}\right\| \leq\left\|\eta_{0}\right\| \exp \left\{-\int_{0}^{\tau}\left[D_{2}-G(\lambda) \Xi\left(\theta_{t} \omega\right)\right] d t\right\}$, which yields

$$
\begin{aligned}
\left\|\bar{y}_{\tau}-y_{\tau}\right\| & \leq(1+\lambda) \exp \left\{-\int_{0}^{\tau}\left[D_{2}-G(\lambda) \Xi\left(\theta_{t} \omega\right)\right] d t\right\}\left\|\bar{y}_{0}-y_{0}\right\| \\
& \leq \exp \left\{\lambda-\int_{0}^{\tau}\left[D_{2}-G(\lambda) \Xi\left(\theta_{t} \omega\right)\right] d t\right\}\left\|\bar{y}_{0}-y_{0}\right\| .
\end{aligned}
$$

By constructing the sequence of stopping times $\left\{\tau_{i}\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x},[0,1]\right)\right\}$ and using induction (taking into account the shift property (3.2)), we derive

$$
\begin{equation*}
\left\|\bar{y}_{1}-y_{1}\right\| \leq \exp \{-D_{2}+[\underbrace{\left.\lambda N\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x},[0,1]\right)+G(\lambda) \int_{0}^{1} \Xi\left(\theta_{t} \omega\right) d t\right]}_{=: \Delta(\lambda, \mathbf{x}(\omega))}\}\left\|\bar{y}_{0}-y_{0}\right\| . \tag{3.38}
\end{equation*}
$$

This proves (3.37). The integrability of $\Delta(\lambda, \cdot)$ follows from the integrability of $\|\mathbf{x}(\cdot)\|_{p-\operatorname{var},[0,1]}$ and of $\Xi(\cdot)$ (which is a consequence of the integrability of $|\mathcal{A}(\cdot)|^{\rho}$ for any $\rho \geq 1$ ).

Next, take any two different points (if any) $a_{1} \neq a_{2} \in \mathcal{A}(\omega)$, we can also write $a_{1}(\omega), a_{2}(\omega) \in$ $\mathcal{A}(\mathbf{x}(\omega))$ for a little abuse of notation to address the dependence on the path $\mathbf{x}$. For a given $n \in \mathbb{N}$, $\operatorname{assign} \mathbf{x}^{*}:=\mathbf{x}\left(\theta_{-n} \omega\right)$ and consider the equation

$$
d y_{t}=f\left(y_{t}\right) d t+g\left(y_{t}\right) d x_{t}^{*}
$$

where $\mathbf{x}^{*}=\left(x^{*}, \mathbb{X}^{*}\right)$. Due to the invariance of $\mathcal{A}(\omega)$ under the flow, there exist $b_{1}, b_{2} \in \mathcal{A}\left(\mathbf{x}^{*}\right)$ such that $a_{i}=y_{n}\left(\mathbf{x}^{*}, b_{i}\right)$. We write in short $y_{t}^{1}=y_{t}\left(\mathbf{x}^{*}, b_{1}\right)$. Then by (3.37) and induction, one can use the shift property (3.3) to show that

$$
\begin{align*}
\left\|a_{2}(\omega)-a_{1}(\omega)\right\| & \leq \exp \left\{-D_{2} n+\sum_{k=0}^{n-1} \Delta\left(\lambda, \mathbf{x}^{*}\left(\theta_{k} \omega\right)\right)\right\}\left\|b_{2}-b_{1}\right\| \\
& \leq 2 \exp \left\{-n\left[D_{2}-\frac{1}{n} \sum_{k=1}^{n} \Delta\left(\lambda, \mathbf{x}\left(\theta_{-k} \omega\right)\right)\right]\right\}\left(|\mathcal{A}|+R\left(\theta_{-n} \omega\right)\right) \tag{3.39}
\end{align*}
$$

Applying Birkhorff ergodic theorem and using (3.38), one gets

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^{n} \Delta\left(\lambda, \mathbf{x}\left(\theta_{-k} \omega\right)\right) & =\mathbb{E} \Delta(\lambda, \mathbf{x}(\cdot)) \\
& =\lambda \mathbb{E} N\left(\frac{\lambda}{16 C_{p} C_{g}}, \mathbf{x}(\cdot),[0,1]\right)+G(\lambda) \mathbb{E} \int_{0}^{1} \Xi\left(\theta_{t} \cdot\right) d t \quad \text { a.s. }
\end{aligned}
$$

where the second term in the right hand side is small by choosing $\lambda$ small enough. Meanwhile, the first term can be controlled as small as possible by choosing $\lambda:=C_{g}$ for sufficiently small $C_{g}$ so that $N$ is fixed to $N\left(\frac{1}{16 C_{p}}, \mathbf{x},[0,1]\right)$. On the other hand $|\mathcal{A}|+R\left(\theta_{-n} \omega\right)$ is a tempered random variable. Hence for sufficiently small $C_{g}$, the right hand side of (3.39) tends to zero exponentially as $n$ tends to infinity a.s., which proves that $\mathcal{A}(\omega)$ is a singleton a.s.

Finally, because $D_{1}=0$, the constants $\bar{C}_{\lambda}$ and $C_{\lambda}$ in the proof of Theorem 2.2 vanish at $\lambda=0$. Hence $\xi_{1}$ and $R$ are functions of $C_{\lambda}$ and can be as small as possible by choosing $\lambda=C_{g}$ for small enough $C_{g}$ so that $N$ in (2.21) is fixed to $N\left(\frac{1}{16 C_{p}}, \mathbf{x},[0,1]\right)$. This proves the upper semi-continuity (3.17).

### 3.3 Discussion on estimation of $\mathbb{E} N(\lambda, \mathbf{x}(\cdot),[0,1])$

Estimate (3.39) in the proof of Theorem 3.7 leads to the question whether the conclusion still holds for any $C_{g}$. To get an answer, we need to check if the following limit is zero

$$
\begin{equation*}
\limsup _{\lambda \rightarrow 0} \lambda \mathbb{E} N(\lambda, \mathbf{x}(\cdot),[0,1]) . \tag{3.40}
\end{equation*}
$$

A direct computation shows that

$$
\begin{aligned}
& \mathbb{E} N(\lambda, \mathbf{x}(\cdot),[0,1]) \\
= & \sum_{n=1}^{\infty} n \mathbb{P}\{\omega: N(\lambda, \mathbf{x}(\cdot),[0,1])=n\} \\
= & \sum_{n=1}^{\infty} n(\mathbb{P}\{\omega: N(\lambda, \mathbf{x}(\cdot),[0,1])>n-1\}-\mathbb{P}\{\omega: N(\lambda, \mathbf{x}(\cdot),[0,1])>n\}) \\
= & \sum_{n=0}^{\infty} \mathbb{P}\{\omega: N(\lambda, \mathbf{x}(\cdot),[0,1])>n\} .
\end{aligned}
$$

Therefore at a first try, we would like to estimate the limit (3.40) for Gaussian noises. Unfortunately, we will show below that simply applying the estimate of $N(\lambda, \mathbf{x},[0,1])$ in [5] would lead to a failure.

More specifically, following [13, Chapter $10 \&$ Chapter 11], let $\mathcal{W}=C\left(I, \mathbb{R}^{m}\right)$ be the probability space equipped with a Gaussian measure $\mathbb{P}$ and let $\left(X_{t}\right)$ be a continuous centered Gaussian process. The associated Cameron-Martin space $\mathcal{H} \subset \mathcal{W}$ consists of paths $t \mapsto h$. $=E\left(Z X\right.$.), where $Z \in \mathcal{W}^{1}$ is an element in the so-called first Wiener chaos. If $\bar{h} .=E(\bar{Z} X$.$) denotes another element in \mathcal{H}$ then the inner product $\langle h, \bar{h}\rangle_{\mathcal{H}}:=E(Z \bar{Z})$ makes $\mathcal{H}$ a Hilbert space and $Z \mapsto h$ is an isometry between $\mathcal{W}^{1}$ and $\mathcal{H}$. The triple $(\mathcal{W}, \mathcal{H}, \mathbb{P})$ is then called the abstract Wiener space. It follows from [13, Proposition 11.2] that given the covariance property (3.4), $\mathcal{H}$ is continuously embedded in the space of continuous paths of finite $q$-variation, i.e. $\mathcal{H} \hookrightarrow C^{q-\operatorname{var}}\left([0,1], \mathbb{R}^{d}\right)$, and there exists a constant $C_{\text {emb }}>0$ such that

$$
\begin{equation*}
\|h\|_{q-\operatorname{var},[s, t]} \leq\|h\|_{\mathcal{H}} \sqrt{\|R\|_{q-\mathrm{var},[s, t]^{2}}} \leq C_{\mathrm{emb}}\|h\|_{\mathcal{H}}, \quad \forall h \in \mathcal{H}, \forall 0 \leq s<t \leq 1 . \tag{3.41}
\end{equation*}
$$

It then makes sense (see e.g. [14] or [5]) to define the so-called translated rough path $T_{h} \mathbf{x}$ as

$$
T_{h} \mathbf{x}:=\left(x+h, \mathbb{X}+\int h \otimes d x+\int x \otimes d h+\int h \otimes d h\right) .
$$

According to [5], $T_{h}: C^{p-\mathrm{var}} \rightarrow C^{p-\mathrm{var}}$ satisfies the estimate

$$
\begin{equation*}
\left\|T_{h} \mathbf{x}\right\|_{p-\operatorname{var},[s, t]} \leq \bar{C}_{p}\left(\|\mathbf{x}\|_{p-\mathrm{var},[s, t]}+\|h\|_{q-\mathrm{var},[s, t]}\right), \quad \forall 0 \leq s<t \leq 1 \tag{3.42}
\end{equation*}
$$

In addition, assume that $X$ has a natural lift to a geometric $p$ - variation rough path $\mathbf{X}$. It is proved in [5, Proposition 6.2, Theorem 6.3] that there exists a set $E \subset \mathcal{W}$ of $\mathbb{P}$-full measure, with the property

$$
\begin{aligned}
\forall \omega \in E, \forall h \in \mathcal{H}, \forall \lambda>0: & \text { if }\|\mathbf{X}(\omega-h)\|_{p-\operatorname{var},[0,1]} \leq \lambda \\
& \text { then }\|h\|_{q-\mathrm{var},[0,1]}^{q} \geq N\left(2 \bar{C}_{p} \lambda, \mathbf{X}(\omega),[0,1]\right) .
\end{aligned}
$$

Moreover,

$$
\begin{equation*}
\mathbb{P}\left\{\omega: N\left(2 \bar{C}_{p} \lambda, \mathbf{X}(\omega),[0,1]\right)>n\right\} \leq \exp \left\{2 a_{\lambda}^{2}\right\} \exp \left\{\frac{-\lambda^{2} n^{\frac{4}{p}}}{2 C_{\mathrm{emb}}^{2}}\right\}, \tag{3.43}
\end{equation*}
$$

where $C_{\text {emb }}$ and $\bar{C}_{p}$ are given in (3.41), (3.42) respectively, $\Phi^{-1}$ is the inverse of the standard normal cumulative distribution function and $a_{\lambda}:=\Phi^{-1}\left(\mathbb{P}\left(B_{\lambda}\right)\right)$ where $B_{\lambda}:=\left\{\omega \in \mathcal{W}:\|\mathbf{X}(\omega)\|_{p-\operatorname{var},[0,1]} \leq\right.$ $\lambda\}$. In fact, a closer look shows that (3.43) follows from Borell's theorem [29, Theorem 4.3] and

$$
\mathbb{P}\left\{\omega: N\left(2 \bar{C}_{p} \lambda, \mathbf{X}(\omega),[0,1]\right)>n\right\} \leq 1-\Phi\left(a_{\lambda}+\frac{\lambda n^{\frac{2}{p}}}{C_{\mathrm{emb}}}\right)=\frac{1}{\sqrt{2 \pi}} \int_{a_{\lambda}+\frac{\lambda_{n} \frac{2}{p}}{C_{\mathrm{emb}}}}^{\infty} e^{-\frac{\chi^{2}}{2}} d \chi .
$$

This yields

$$
\begin{equation*}
\limsup _{\lambda \rightarrow 0} 2 \bar{C}_{p} \lambda \mathbb{E} N\left(2 \bar{C}_{p} \lambda, \mathbf{X}(\omega),[0,1]\right) \leq \limsup _{\lambda \rightarrow 0} \frac{2 \bar{C}_{p} \lambda}{\sqrt{2 \pi}} \sum_{n=1}^{\infty} \int_{a_{\lambda}+\frac{\lambda n^{2}}{C_{\text {emb }}}}^{\infty} e^{-\frac{\chi^{2}}{2}} d \chi . \tag{3.44}
\end{equation*}
$$

Unfortunately, the right hand side of (3.44) is infinity for $p \geq 2$. Indeed, observe that $\mathbb{P}\left(B_{\lambda}\right) \rightarrow 0$ as $\lambda \rightarrow 0$, which implies $a_{\lambda} \rightarrow-\infty$ as $\lambda \rightarrow 0$. Thus $a_{\lambda}+\frac{\lambda n^{\frac{2}{p}}}{C_{\text {emb }}} \leq 0$ as long as $n \leq b_{\lambda}:=\left(C_{\text {emb }} \frac{-a_{\lambda}}{\lambda}\right)^{\frac{p}{2}}$. As a result,

$$
\begin{aligned}
\frac{\lambda}{\sqrt{2 \pi}} \sum_{n=1}^{\infty} \int_{a_{\lambda}+\frac{\lambda_{n} \frac{2}{p}}{C_{\mathrm{emb}}}}^{\infty} e^{-\frac{\chi^{2}}{2}} d \chi \geq \frac{\lambda}{\sqrt{2 \pi}} \sum_{n=1}^{b_{\lambda}} \int_{0}^{\infty} e^{-\frac{\chi^{2}}{2}} d \chi & \approx \frac{1}{2} \lambda b_{\lambda} \\
& \approx \frac{1}{2} C_{\mathrm{emb}}^{\frac{p}{2}}\left(-a_{\lambda}\right)^{\frac{p}{2}} \lambda^{1-\frac{p}{2}} \rightarrow \infty
\end{aligned}
$$

as $\lambda \rightarrow 0$, provided that $p \geq 2$. Similarly, an attempt to apply the estimate

$$
\mathbb{P}\left\{\omega: N\left(2 \bar{C}_{p} \lambda, \mathbf{X}(\omega),[0,1]\right)>n\right\} \leq \exp \left\{\delta\left(\mathbb{P}\left(B_{\lambda}\right)\right) \frac{\lambda n^{\frac{2}{p}}}{C_{\mathrm{emb}}}-\frac{\lambda^{2} n^{\frac{4}{p}}}{2 C_{\mathrm{emb}}^{2}}\right\}
$$

where $\delta(v)=\int_{0}^{\infty} \min \left(1-v, e^{-\frac{t^{2} v^{2}}{2}}\right) d t$ as suggested in [29, Formula (4.6), p. 210] also leads to the divergence of a series similar to the one in the right hand side of (3.44). It is therefore a challenging problem on how to estimate the interesting limit (3.40).

## Acknowledgments

The author would like to thank the anonymous referee for valuable remarks which led to an improvement of the paper at this present form. This work was supported by the Max Planck Institute for Mathematics in the Science (MIS-Leipzig). A part of this work was done while the author visited Vietnam Institute for Advanced Studies in Mathematics (VIASM) for a three month research stay in summer 2019.
